Akshat Kumar & Shlomo Zilberstein. MAP Estimation for graphical Models by Likelihood Maximization.
MAP problem for MRF

$$p(x; \theta) = \frac{1}{Z} e^{\sum_{ij \in E} \theta_{ij}(x_i, x_j)}.$$ 

Task: find most probable assignments to all variables = MPE
Paper in a nutshell

- We want to solve MAP problem for Markov Random Fields
- Can formulate as Linear Programming problem
  - Associate a marginal polytop with the MAP problem
  - Exponentially large constraints – difficult to solve
- Well-known LP relaxations to find the upper bound exist
  - Outer bound on the marginal polytop
- Authors propose relaxation to get a lower-bound
  - Inner bound on the marginal polytop
  - Not convex – formulate as a mixture of BN, solve with EM
- → Get fast and pretty accurate approximation method
MAP problem for MRF as LP

\[ p(x; \theta) = \frac{1}{Z} e^{\sum_{i,j \in E} \theta_{ij}(x_i, x_j)} \]

Introduce \( \mu \) - a vector of marginal probabilities for each node and edge of MRF coming from some joint probability \( p \)

\[
\begin{align*}
\mu_s(x_s) &= \begin{bmatrix} \mu_s(0) \\ \mu_s(1) \\ \mu_s(2) \end{bmatrix} \\
\mu_{st}(x_s, x_t) &= \begin{bmatrix} \mu_{st}(0, 0) & \mu_{st}(0, 1) & \mu_{st}(0, 2) \\ \mu_{st}(1, 0) & \mu_{st}(1, 1) & \mu_{st}(1, 2) \\ \mu_{st}(2, 0) & \mu_{st}(2, 1) & \mu_{st}(2, 2) \end{bmatrix}
\end{align*}
\]

\( \mathcal{M}(G) = \{ \mu \mid \exists p(x) \text{ s.t. } p(x_i, x_j) = \mu_{ij}(x_i, x_j), p(x_i) = \mu_i(x_i) \} \)
MAP problem for MRF as LP

\[ p(x; \theta) = \frac{1}{Z} e^{\sum_{ij \in E} \theta_{ij}(x_i, x_j)} \]

\[ \mathcal{M}(G) = \{ \mu \mid \exists p(x) \text{ s.t. } p(x_i, x_j) = \mu_{ij}(x_i, x_j), \ p(x_i) = \mu_i(x_i) \} \]

MAP problem is equivalent to solving:

\[ \max \ f(x; \theta) = \max_{\mu \in \mathcal{M}(G)} \mu \cdot \theta = \max_{\mu \in \mathcal{M}(G)} \sum_{ij \in E} \sum_{x_i x_j} \theta_{ij}(x_i, x_j) \mu_{ij}(x_i, x_j) \]
MAP problem for MRF as LP

\[ p(x; \theta) = \frac{1}{Z} e^{\sum_{i,j \in E} \theta_{ij}(x_i, x_j)} \]

\[ \mu \] should satisfy constraints

\[ \mathcal{M}(G) = \{ \mu \mid \exists p(x) \text{ s.t. } p(x_i, x_j) = \mu_{ij}(x_i, x_j), \ p(x_i) = \mu_i(x_i) \} \]

MAP problem is equivalent to solving:

\[ \max_{x} f(x; \theta) = \max_{\mu \in \mathcal{M}(G)} \mu \cdot \theta = \max_{\mu \in \mathcal{M}(G)} \sum_{i,j \in E} \sum_{x_i x_j} \theta_{ij}(x_i, x_j) \mu_{ij}(x_i, x_j) \]
Marginal polytopes for general undirected models

- $\mathcal{M}(G)$ $\triangleq$ set of all globally realizable marginals $\{\mu_s, \mu_{st}\}$:

$$\left\{ \mu \in \mathbb{R}^d \mid \mu_s(x_s) = \sum_{x_t, t \neq s} p_\mu(x), \text{ and } \mu_{st}(x_s, x_t) = \sum_{x_u, u \neq s, t} p_\mu(x) \right\}$$

for some $p_\mu(\cdot)$ over $(X_1, \ldots, X_N) \in \{0, 1, \ldots, m - 1\}^N$.

- polytope in $d = m|V| + m^2|E|$ dimensions ($m$ per vertex, $m^2$ per edge)
- with $m^N$ vertices
MAP problem for MRF as LP relaxation (upper bound)

- We don't assume anymore that \( \mu \) comes from some distribution \( \rho \)
- Only pairwise and singleton consistently is required

\[
\sum_{x_i} \mu_i(x_i) = 1 \quad \forall i \in V, \sum_{\hat{x}_i} \mu_{ij}(\hat{x}_i, x_j) = \mu_j(x_j)
\]

\[
\sum_{\hat{x}_j} \mu_{ij}(x_i, \hat{x}_j) = \mu_i(x_i) \quad \forall (i, j) \in E \quad (3)
\]

Marginal polytope is expressed by:

\[\mathcal{M}_L(G) = \{\mu \geq 0 \mid \text{The conditions of Eq. 3 hold}\}\]
Inner bound on Marginal Polytope [Ravikumar and Lafferty, 2006]

- No requirement on the structure of global distribution $p$
- Mean-field structure: $p(x) = \prod_{i=1}^{n} p_i(x_i)$
- Inner bound $\mathcal{M}_{lb}(G) = \{\mu\}$ s.t.
  $\mu_i(x_i) = p_i(x_i)$
  $\mu_{ij}(x_i, x_j) = p_i(x_i)p_j(x_j)$

Objective: $\max_{\mu \in \mathcal{M}_{lb}(G)} \sum_{ij \in E} \sum_{x_i x_j} \theta_{ij}(x_i, x_j) \mu_i(x_i) \mu_j(x_j)$
Relationship among formulations

$M_{lb}(G)$

$M(G)$

$M_L(G)$

Integral vertex

Inner bound

Marginal Polytope
Properties of Inner Bound $\mathcal{M}_{ib}(G)$

- Mean field structure: exact or approximate?
- Fact1: $\mathcal{M}_{ib}(G)$ touches $\mathcal{M}(G)$ at integral solution
- Fact2: Optimal solution of $\mathcal{M}(G)$ is also integral
- Optimization over inner bound is exact!
Properties of Inner Bound $\mathcal{M}_{lb}(G)$

Some advantages of the inner bound approach

- Example problem: 170 variables, 150 domain size, 3167 edges
- Constraints in $\mathcal{M}(G)$ exponential
- In outer bound: $\approx 71$ million variables, $\approx 1$ million constraints
- In inner bound: 25500 variables, 170 constraints
- Only normalization constraints, linear in the number of nodes

No free lunch – convexity is lost
Optimization over the inner bound

Objective function to optimize:

$$\max \sum_{ij \in E} \sum_{x_i, x_j} \theta_{ij}(x_i, x_j) p_i(x_i)p_j(x_j)$$

subject to normalization constraint for each variable

- A general nonlinear optimization problem
- Can solve using generic NLP solvers, may not be efficient
- We present an alternate characterization of MAP using Bayes net mixture
- MAP $\equiv$ probabilistic inference over this mixture
MAP as mixture of Bayes Nets

We want to estimate marginal probabilities:

\[ p(l = i) = \frac{1}{k}, ~i \in [1; k] \]

\[ \mathbf{p} = \langle p_1, \ldots, p_n \rangle, \quad p_i = p(x_i) \]
MAP as mixture of Bayes Nets

Example: for \( l = 1 \)

\[
P(\hat{\theta} = 1| x_l, x_{l_2}, l) = \frac{\theta_l(x_l, x_{l_2}) - \theta_{\min}}{\theta_{\max} - \theta_{\min}}
\]

Full joint for a particular Bayes Net indicated by \( l \):

\[
P(\hat{\theta}, x_l | l; p) = P(\hat{\theta}| x_l, x_{l_2}, l)p_L(x_l_1; p)p_l_2(x_l_2; p)
\]
Some notation:

$$x_l = (x_{l_1}, x_{l_2})$$
$$\hat{\theta}_{x_l} = P(\hat{\theta} = 1|x_{l_1}, x_{l_2}, l)$$
$$\theta_l :$$
Some notation:

\[ x_l = (x_{l_1}, x_{l_2}) \]
\[ \hat{\theta}_{x_l} = P(\hat{\theta} = 1 | x_{l_1}, x_{l_2}, l) \]
\[ \theta_l : \]
Some notation:

\[ x_l = (x_{l1}, x_{l2}) \]
\[ \hat{\theta}_{x_l} = P(\theta = 1| x_{l1}, x_{l2}, l) \]
\[ \theta_l : \]
Some notation:

\[ x_l = (x_{l1}, x_{l2}) \]
\[ \hat{\theta}_{x_l} = P(\theta = 1|x_{l1}, x_{l2}, l) \]
\[ \theta_l : \]
\[ x_l = (x_{l1}, x_{l2}) \]
\[ \hat{\theta}_{x_l} = P(\hat{\theta} = 1 | x_{l1}, x_{l2}, l) \]

**Theorem**

Maximizing the likelihood of observing \( \hat{\theta} = 1 \) in the mixture optimizes the original objective function.

Objective: 
\[
\max \sum_{ij \in E} \sum_{x_i x_j} \theta_{ij}(x_i, x_j) p_i(x_i) p_j(x_j)
\]

\[
\max_{\mathbf{\theta}} f_{lb}(x; \mathbf{\theta}) = \max_{\mathbf{\mu} \in \mathcal{M}_{lb}(G)} \mu \cdot \mathbf{\theta} = \max_{\mathbf{\mu} \in \mathcal{M}_{lb}(G)} \sum_{ij \in E} \sum_{x_i x_j} \theta_{ij}(x_i, x_j) \mu_i(x_i) \mu_j(x_j)
\]
Theorem
Maximizing the likelihood of observing $\hat{\theta} = 1$ in the mixture optimizes the original objective function.

Objective: $\max \sum_{ij \in E} \sum_{x_i x_j} \theta_{ij}(x_i, x_j)p_i(x_i)p_j(x_j)$

Proof.
Likelihood for a single Bayes net

$L_{ij} = P(\hat{\theta} = 1|(i, j)) = \sum_{x_i x_j} \hat{\theta}_{ij}(x_i, x_j)p_i(x_i)p_j(x_j) = \sum_{x_i} \hat{\theta}_{x_i} p_{l_1}(x_1; p)p_{l_2}(x_2; p)$

For the complete mixture

$L = \sum_{(i, j)} P(l)L_{ij} = \frac{1}{|E|} \sum_{(i, j)} \sum_{x_i x_j} \hat{\theta}_{ij}(x_i, x_j)p_i(x_i)p_j(x_j)$

Objective: $\sum_{ij \in E} \sum_{x_i x_j} \theta_{ij}(x_i, x_j)p_i(x_i)p_j(x_j) = \frac{1}{k} \sum_{l} \sum_{x_i} \hat{\theta}_{x_i} p_{l_1}(x_1; p)p_{l_2}(x_2; p)$

$L \propto \text{Objective} \quad \Box$
That's the likelihood of BN mixture from previous slide:

$$\sum_l \sum_{x_l} \theta_l(x_l)p_l(x_l_1; p)p_l(x_l_2; p) = k(\theta_{min} + (\theta_{max} - \theta_{min})L^p).$$

And that's our optimization criterion for lower bound:

$$\max_{\mu \in M_{lb}(G)} \sum_{i,j \in E} \sum_{x_i x_j} \theta_{ij}(x_i, x_j)\mu_i(x_i)\mu_j(x_j)$$

Recalling that

$$\theta_l(x_l) = \theta_{i,j}(x_i, x_j)$$

and

$$p_l(x_l_1; p) = \mu_i(x_i)$$

These are the same things

So, can maximize $L^p$ and get MAP lower bound!

Let's use EM for that
The EM Algorithm

- Maximum likelihood parameter estimates
  - One definition of the "best" knob settings.
  - Often impossible to find directly.

- The EM algorithm:
  - Finds ML parameters when the original (hard) problem can be broken up into two (easy) pieces, i.e., finds the ML estimates of parameters for data in which some variables are unobserved.
  - A iterative method which consists of "Expectation step" (E-step) and "Maximization step" (M-step).
    1. Estimate some "missing" or "unobserved" data from observed data and current parameters (E-step)
    2. Using this "complete" data, find the maximum likelihood parameter estimates (M-step).
Graphical illustration for auxiliary function
EM for MAP Estimation

Basic idea

- Treat all variables $x_i$ as hidden
- Observed data $\hat{\theta} = 1$
- Estimate $\mu_i$ for each variable $i$
- Update equations easily implemented using graph-based message passing
Update rules

Expected complete log-likelihood:

\[ Q(p, p^*) = \sum_l \sum_{x_i} P(\hat{\theta} = 1, x_l, l; p) \log P(\hat{\theta} = 1, x_l, l; p^*) \]

The full joint is given by:

\[ P(\hat{\theta} = 1, x_l, l; p) = P(\hat{\theta} = 1|x_l, l)P(x_l|l; p)P(l) = \frac{1}{k}\hat{\theta}_{x_l}p_{l_1}(x_{l_1}; p)p_{l_2}(x_{l_2}; p) \]

We will omit the parameter \( p \) whenever the expression is unambiguous. Taking the log, we get:

\[ \log P(\hat{\theta} = 1, x_l, l; p) = \langle \text{Ind. terms of } p \rangle + \log p_{l_1}(x_{l_1}) + \log p_{l_2}(x_{l_2}) \]  \hspace{1cm} (12)

Substituting the above equation into the definition of \( Q(p, p^*) \) (Eq. 11) and discarding the terms which are independent of \( p^* \), we get:

\[ Q(p, p^*) = \frac{1}{k} \sum_l \sum_{x_i} \hat{\theta}_{x_l}p_{l_1}(x_{l_1})p_{l_2}(x_{l_2})\{\log p_{l_1}^*(x_{l_1}) + \log p_{l_2}^*(x_{l_2})\} \]  \hspace{1cm} (13)

Upon simplifying the above equation by grouping together the terms associated with the variables \( x_i \) of the MRF, we get:

\[ Q(p, p^*) = \frac{1}{k} \sum_{i=1}^n \sum_{x_i} p_i(x_i) \log p_i^*(x_i) \sum_{j \in N_e(i)} \sum_{x_j} \hat{\theta}_{x_i x_j}p_j(x_j) \]  \hspace{1cm} (14)

\[ p_i^*(x_i) = \frac{p_i(x_i) \sum_{j \in N_e(i)} \sum_{x_j} \hat{\theta}_{x_i x_j}p_j(x_j)}{C_i} \]
Update rules

Expected complete log-likelihood:

\[ Q(p, p^*) = \sum_l \sum_{x_l} P(\hat{\theta} = 1, x_l, l; p) \log P(\hat{\theta} = 1, x_l, l; p^*) \]

The full joint is given by:

\[ P(\hat{\theta} = 1, x_l, l; p) = P(\hat{\theta} = 1 | x_l, l) P(x_l | l; p) P(l) = \frac{1}{k} \hat{\theta}_{x_l} p_{l_1}(x_{l_1}; p) p_{l_2}(x_{l_2}; p) \]

We will omit the parameter \( p \) whenever the expression is unambiguous. Taking the log, we get:

\[ \log P(\hat{\theta} = 1, x_l, l; p) = \langle \text{Ind. terms of } p \rangle + \log p_{l_1}(x_{l_1}) + \log p_{l_2}(x_{l_2}) \] (12)

Substituting the above equation into the definition of \( Q(p, p^*) \) (Eq. 11) and discarding the terms which are independent of \( p^* \), we get:

\[ Q(p, p^*) = \frac{1}{k} \sum_l \sum_{x_l} \hat{\theta}_{x_l} p_{l_1}(x_{l_1}) p_{l_2}(x_{l_2}) \{ \log p_{l_1}^*(x_{l_1}) + \log p_{l_2}^*(x_{l_2}) \} \] (13)

Upon simplifying the above equation by grouping together the terms associated with the variables \( x_i \) of the MRF, we get:

\[ Q(p, p^*) = \frac{1}{k} \sum_{i=1}^{n} \sum_{x_i} p_i(x_i) \log p_i^*(x_i) \sum_{j \in Ne(i)} \sum_{x_j} \hat{\theta}_{x_i x_j} p_j(x_j) \] (14)

\[ p_i^*(x_i) = \frac{p_i(x_i) \sum_{j \in Ne(i)} \sum_{x_j} \hat{\theta}_{x_i x_j} p_j(x_j)}{C_i} \]

M-step
Message Passing in EM

- E-step of EM
- Node $j$ sends message $\delta_{j\to i}(x_i)$ to its neighbor $i$
- $\delta_{j\to i}(x_i) = \sum_{x_j} \mu_j(x_j) \hat{\theta}_{ij}(x_i, x_j)$
- Weighted normalized reward
- Local message passing, scalable, efficient
M-Step in EM

- Each variable collects all incoming messages
- Update: \( \mu^*(x_i) = \mu_i(x_i) \frac{\sum_{k \in Ne(i)} \delta_{k \rightarrow i}(x_i)}{C_i} \)
- Computational complexity \( O(nd^2) \)
Algorithm

Algorithm 1: Graph-based message passing for MAP estimation

input : Graph $G = (V, E)$ for the MRF and potentials $\theta$ for each edge
repeat
    foreach node $i \in V$ do
        EM: Send message $\delta_{i \rightarrow j}$ to each neighbor $j \in Ne(i)$
        \[ \delta_{i \rightarrow j}(x_j) \leftarrow \sum_{x_i} p_i(x_i) \hat{\theta}_{x_i x_j} \]
        Set marginal probability to sum of incoming messages:
        \[ p_i^*(x_i) = p_i(x_i) \frac{\sum_{k \in Ne(i)} \delta_{k \rightarrow i}(x_i)}{C_i} \]
    until stopping criterion is satisfied
    EM : Return complete assignment $\hat{x}$ s.t. $x_i = \arg\max_{\hat{x}_i} p_i(\hat{x}_i)$

Complexity of computing a single message is $O(d^2)$, were $d$ - domain size

**Independent of degree ???**
Experiments

Protein design dataset – 97 instances
Comparisons with Max-Product LP [Sontag et al., 2008],
Max-Product [Pearl, 1988]
Mean running time MPLP– 9.7 hours, EM only 300 seconds.
EM produces better solution quality much faster than MPLP
Experiment: solution quality
Experiments

1fpo
N=170, C=3167

</table>
Why is this method good?

- Average solution quality within 95% of optimal (for protein design)
- Increases lower bound on MAP rapidly
- Embarassingly parallel
  - (assuming shared memory? o.w. too much communication)
- Doesn't work:
  - \( \Theta_{\text{max}} - \Theta_{\text{min}} \) is large
