Quiz 6

To get credit for this quiz, use the Quiz tool at eee.uci.edu to enter your answers, within the Sunday-to-Tuesday quiz period.

Problem 1 (4 points)

(a) (4 points) A quiz has scores in the range 0 to 10. We can represent the distribution of scores on this quiz as a list of numbers, each number being the count of students who received a particular score. So in the list below, 1 person scored 0, 3 people scored 5, and 45 people scored 10:

```
counts = [1, 0, 0, 2, 2, 3, 8, 22, 33, 40, 45]
```

Suppose we want to print these statistics in a table in the following format:

```
0. 1 (0.64%)
1. 0 (0.00%)
2. 0 (0.00%)
3. 2 (1.28%)
4. 2 (1.28%)
5. 3 (1.92%)
6. 8 (5.13%)
7. 22 (14.10%)
8. 33 (21.15%)
9. 40 (25.64%)
10. 45 (28.85%)
```

In the following code, fill in each blank with one character so that the output is formatted as shown above.

```
TOPSCORE = 10
for s in range(TOPSCORE + 1):
    print("{:____d}. {:3d} ({:___.___}}%)".format(s, counts[s], counts[s]/sum(counts)*100))
```

In the following code, fill in each blank with one character so that the output is formatted as shown above.

```
TOPSCORE = 10

for s in range(TOPSCORE + 1):
    print(f"{s:____d}. {count[s]:3d} ({count[s]/sum(counts)*100:____. ____}%)")
```

(b) (4 points) Suppose we want to print a simple bar graph with the table of statistics:

Rewrite the code above to produce the bar graph as shown.

Problem 2 (10 points)

Suppose we wish to process text files that contain some "front matter"—lines at the start of the file that we wish to ignore, similarly to a part of this week's lab. Let's say that we have read the file into a list of strings, that the end of the front matter is indicated by a line in the file that says "END OF FRONT MATTER", and that we are guaranteed that this line will occur in the file.

Complete the definition of remove_front_matter below, consistent with its header, docstring, and assertions. [Recall that the annotation [str] means the same things as 'list of str'. Note that no actual file-handling commands are required for this solution.]

```
def remove_front_matter(linelist: [str]) -> [str]:
    ''' Return input list with starting lines (through "END OF FRONT MATTER") removed
    '''
```

Problem 3 (6 points)

Complete the definition of seconds_to_mmss below, consistent with its header, docstring, and assertions. [Note: The integer division operator (a//b) gives the integer quotient of a/b. The mod operator (%) gives the remainder of a/b.] You do not have to worry about leading zeroes (like "11:05").

```
def seconds_to_mmss(seconds: int) -> str:
    ''' Convert a number of seconds to minutes and seconds in "mm:ss" format
    '''

assert(seconds_to_mmss(15) == "0:15")
assert(seconds_to_mmss(75) == "1:15")
assert(seconds_to_mmss(3620) == "60:20")
```

Problem 4 (10 points)

Parts of this excerpt from help(str) may be useful in this problem:

```
find(...)
    S.find(sub) -> int
    Return the lowest index in S where the string sub is found.
    Return -1 on failure.

split(...)
    S.split(sep) -> list of strings
    Return a list of the words in S, using sep as the delimiter string.

strip(...)
    S.strip() -> str
    Return a copy of the string S with leading and trailing whitespace removed.
```

Complete the function definition below, consistent with its header, docstring, and assertions.

```
assert (mmddyy_to_MonthDayYear('10/31/15') == 'October 31, 2015') assert (mmddyy_to_MonthDayYear('12/1/07') == 'December 1, 2007') assert (mmddyy to MonthDayYear('1/3/99') == 'January 3, 2099')
```

Problem 5 (11 points)

Suppose we have a list of scores on a quiz, one score for each student, in the range 0 to 20. For example:

```
quiz scores = [18, 20, 18, 20, 0, 10, 10, 20, 10, 20]
```

We would like to produce a list of counts, one count for each possible score

(a) (4 points) Write the function zero_counts that takes a number (such as the number of points on a quiz) and returns a list of zeros, one zero for each possible score).

```
def zero_counts (top_value: int) -> 'list of int':
    ''' Return a list of zeroes, with one zero for each possible score from zero to
        top_value
    '''
```

```
assert zero_counts(10) == [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]
assert zero_counts(0) == [0]
```

- **(b)** (3 points) In one sentence, why does zero_counts(10) return a list of eleven zeroes?
- (c) (4 points) Now, write the function count_scores that takes a list of scores and a number that represents the highest possible score; it returns a list of counts, indicating how many times each score occurred:

```
assert count_scores([], 5) == [0, 0, 0, 0, 0, 0]
assert count_scores(quiz_scores, 20) == quiz_counts
```
