Second Midterm

You have 75 minutes (until the end of the class period) to complete this exam. There are 55 points possible, so allow approximately one minute per point and you’ll have plenty of time left over.

Please read all the problems carefully. If you have a question on what a problem means or what it calls for, ask us. Unless a problem specifically asks about errors, you should assume that each problem is correct and solvable; ask us if you believe otherwise.

In answering these questions, you may use any Python 3 features we have covered in class, in the text, in the lab assignments, or earlier on the exam, unless a problem says otherwise. Use more advanced features at your own risk; you must use them correctly. If a question asks for a single item (e.g., one word, identifier, or constant), supplying more than one will probably not receive credit.

Remember, stay cool! If you run into trouble on a problem, go on to the next one. Later on, you can go back if you have time. Don’t let yourself get stuck on any one problem.

You may not share any information or materials with classmates during the exam and you may not use any electronic devices.

Please write your answers clearly and neatly—we can’t give you credit if we can’t decipher what you’ve written.

We’ll give partial credit for partially correct answers, so writing something is better than writing nothing. But be sure to answer just what the question asks.

Good luck!
Problem 1 (9 points) Topic: String processing

U.S. telephone numbers can appear in many forms:

949-824-5072  (949)824-5072  9498245072  1-949-824-5072  1(949)824-5072  +1(949)824-5072

To process a collection of phone numbers, it’s helpful if we store every number in the same form. Below is the outline of a function to perform this task; it shows three steps labeled (a), (b), and (c).

def phone_number_to_10_digits(original: str) -> str:
    """ Convert the parameter to a string of exactly 10 digits """
    # (a) Change all punctuation to blanks
    # (b) Remove all blanks
    # (c) Remove extra 1 at beginning if necessary
    return result

assert phone_number_to_10_digits('+1(999)888-7777') == '9998887777'
assert phone_number_to_10_digits('1-999-888-7777') == '9998887777'
assert phone_number_to_10_digits('1(999)888-7777') == '9998887777'
assert phone_number_to_10_digits('9998887777') == '9998887777'
assert phone_number_to_10_digits('(999)888-7777') == '9998887777'
assert phone_number_to_10_digits('999-888-7777') == '9998887777'

The following excerpt from help(str) may be useful for this problem.

find(...)  
S.find(sub) -> int  
Return the lowest index in S where substring sub is found.  
Return -1 on failure.

replace(...)  
S.replace(old, new) -> str  
Return a copy of S with all occurrences of substring old replaced by new.

maketrans(...)  
str.maketrans(x, y) ->  
dict (static method)  
Return a translation table usable for translate(). The arguments must be strings of equal length, and in the resulting dictionary, each character in x will be mapped to the character at the same position in y.

translate(...)  
S.translate(table) -> str  
Return a copy of the string S, where all characters have been mapped through the given translation table. Unmapped characters are left untouched.

upper(...)  
S.upper() -> str  
Return a copy of S converted to uppercase.

(a) Which of the following code segments correctly implements step (a) above? Circle one or more of A, B, C, or D; more than one may be correct.

A. result = original.replace("()-+", "    ")
B. result = translate("()-+-", "    ")
C. table = str.maketrans("()-+", "    ")  
   result = original.translate(table)  
   #THIS (2 lines)
D. result = original.translate(str.maketrans("()-+", "    "))  
   #THIS
(b) Which of the following code segments correctly implements step (b) above? Circle one or more of A, B, C, or D; more than one may be correct.

A. \texttt{result = result.strip()}  
B. \texttt{result.replace(" ", None)}  
C. \texttt{result = result.lstrip().rstrip()}  
D. \texttt{result = result.replace(" ", "") \quad \#THIS}  

(c) Which of the following code segments correctly implements step (c) above? Circle one or more of A, B, C, or D; more than one may be correct.

A. \texttt{if len(result) > 10 and result[0] == '1': \quad \#THIS}  
B. \texttt{if len(result) > 10 and result[0] == '1':}  
\hspace{1em} \texttt{result = result - 1}  
C. \texttt{if len(result) > 10 and result[0] == '1':}  
\hspace{1em} \texttt{del result[0]}  
D. \texttt{if len(result) > 10 and result[0] == '1':}  
\hspace{1em} \texttt{result = result - '1'}  

Problem 2 (18 points) Topic: Processing lists of namedtuples

A government agency has asked your help in building a system for analyzing telephone call records. You represent a single phone call as follows:

\texttt{Call = namedtuple('Call', 'num_from num_to date time seconds')}  

\noindent \textbf{where} \texttt{num_from} and \texttt{num_to} are strings representing 10-digit US phone numbers (the caller’s number is \texttt{num_from}; the number dialed is \texttt{num_to}), \texttt{date} is a string representing the date, \texttt{time} represents the time the call was made, and \texttt{seconds} represents how long the call lasted, in seconds.

\texttt{c1 = Call('7142220000', '9494440000', '01/23/2014', '12:32', 240)}  
\texttt{c2 = Call('7142220000', '8189990000', '01/23/2014', '12:37', 200)}  
\texttt{c3 = Call('3132221111', '2121112222', '01/24/2014', '08:25', 1600)}  
\texttt{all_calls = [c1, c2, c3]}  

(a) (5 points) Complete the definition of the function below, consistent with its header, docstring comment, and assertions, by filling each blank with exactly one identifier, operator, or constant. (Remember that [Call] as a type annotation is the same as 'list of Call'.)

\texttt{def calls_from(call_list: [Call], phone_number: str) \rightarrow [Call]:}  
\noindent \texttt{\"\"\" Return a list of all calls made from the specified number \"\"\"}  
\noindent \texttt{for c in \hspace{1em} \vdots}  
\noindent \texttt{\hspace{2em} if c.num_from == phone_number:}  
\noindent \texttt{\hspace{3em} result.append(c)}  
\noindent \texttt{return result}  

assert calls_from(all_calls, '7142220000') == [c1, c2]  
assert calls_from(all_calls, '3132221111') == [c3]  
assert calls_from(all_calls, '9999999999') == [ ]
(b) (2 points) Next, define a similar function named `calls_to()` that returns calls made to a specified number, as described below. The body of `calls_to()` could be identical to the body of `calls_from()` above, except for one identifier in one place. Fill in the changed identifier below and leave the other places blank.

```python
def calls_to(call_list: [Call], phone_number: str) -> [Call]:
    """ Return a list of all calls made to the specified number
    ""
    result = [ ]
    for c in ____________:
        if c.____________ == ____________:
            # ANSWER: c.num_to instead of c.num_from.
            ____________.append(____________)
    return result

assert calls_to(all_calls, '7142220000') == [ ]
assert calls_to(all_calls, '2121112222') == [c3]
assert calls_to([ ], '3132221111') == [ ]
```

(c) (4 points) We plan to use this software to identify people who call the numbers of known terrorists (or receive calls from terrorists’ numbers). Next we’ll write a version of `calls_from()` that selects calls from any phone number on a list of numbers (rather than from just a single number). Complete the definition of the function below, consistent with its header, docstring comment, and assertions, by filling each blank with exactly one identifier, operator, or constant.

```python
def calls_from_any(call_list: [Call], suspected_numbers: [str]) -> [Call]:
    """ Return a list of all calls made from a number on the suspected_numbers list.
    ""
    result = [ ]
    for c in ____________:
        for c in call_list:
            if c.____________  ____________  ____________:
                if c.num_from in suspected_numbers:
                    ____________.append(____________)
                    result.append( c )
    return result

assert calls_from_any(all_calls, ['7142220000', '3132221111', '7778881111']) == [c1, c2, c3]
```

(d) (2 points) Next, define a function named `calls_to_any()` that returns a list of all calls made to a number on the suspected-number list. The body of `calls_to_any()` could be identical to the body of `calls_from_any()`, except for one identifier in one place. Fill in the changed identifier below and leave the other places blank.

```python
def calls_to_any(call_list: [Call], suspected_numbers: [str]) -> [Call]:
    """ Return a list of all calls made to a number on the suspected_numbers list.
    ""
    result = [ ]
    for c in ____________:
        # ANSWER (next line): c.num_to instead of c.num_from.
        if c.____________  ____________  ____________:
            ____________.append(____________)
    return result

assert calls_to_any(all_calls, ['7142220000', '8189990000', '2121112222']) == [c2, c3]
```
(e) (5 points) Complete the definition of the function below, consistent with its header, docstring comment, and assertions, by filling in each blank with exactly one identifier, operator, or constant.

```python
def total_call_time(call_list: [Call]) -> int:
    """Return the total duration of all calls on list (in seconds)"
    result = ____________  # result = 0
    for c in ____________:
        ____________ += ____________ . ____________  # result += c.seconds
    return ____________  # return result
assert total_call_time(all_calls) == 2040
assert total_call_time([c1]) == 240
assert total_call_time([]) == 0
```

**Problem 3 (5 points)** Topic: String formatting

(a) (3 points) The function below prints all the calls from a given number in a formatted table:

```python
def print_calls_from(whole_call_list: [Call], phone_number: str) -> None:
    """Print all the calls from the specified number in table form."
    selected_calls = calls_from(whole_call_list, phone_number)
    print('From       To         Date       Time  Seconds  Minutes')
    print()  
    FORMAT_STRING = — Choose the correct value from A–E below —
    for c in selected_calls:
        print(FORMAT_STRING.format(c.num_from, c.num_to, c.date, c.time,
                                    c.seconds, c.seconds / 60))
```

Choose which one of these five values could go in the code above to produce the correct formatting. Circle one of A, B, C, D, or E; only one is correct.

A. "{:15s} {:15s} {:15s} {:5s} {:7d} {:8.3f}"
B. "{:10s} {:10s} {:15s} {:5s} {:1d} {:2.3f}"
C. "{:10s} {:10s} {:10s} {:5s} {:1d} {:8.3f}"
D. "{:10s} {:10s} {:10s} {:5s} {:7d} {:8.3f}"  # THIS ONE
E. "{:10s} {:10s} {:10s} {:5s} {:7d} {:2.3f}"

(b) (2 points) Which of the following is the correct output from this print statement:

```python
print("Call time is {:2d} seconds.").format(120))
```

Circle one of A, B, C, D, or E; only one is correct.

A. Call time is 12 seconds.
B. Call time is 20 seconds.
C. Call time is 120 seconds.
D. Call time is 120 seconds.  # THIS ONE
E. Call time is 120 seconds.
Problem 4 (20 points)  **Topic: Processing lists of namedtuples**

The previous problems dealt with a list containing every call. It will be convenient to organize those calls by customer (i.e., by the person who "owns" each phone number), with a record (namedtuple) for each person. Each record starts out as follows:

```python
Customer = namedtuple('Customer', 'name address phone outgoing incoming')
p1 = Customer('Jones, John', '12 Elm St.', '9494440000', [], [])
p2 = Customer('Smith, Sally', '24 Oak St.', '7142220000', [], [])
p3 = Customer('Roberts, Dan', '36 Ash St.', '2137770000', [], [])
p4 = Customer('Brown, Mary', '48 Fir St.', '8189990000', [], [])
```

where the name, address, and phone are strings. The last two fields are lists: a list of all the (outgoing) Calls made from the customer’s number and a list of all the (incoming) Calls made to the customer’s number.

(a) (5 points) First we write a function that completes the outgoing and incoming call lists for a single customer. Complete the definition of the function below, consistent with its header, docstring comment, and assertions, by filling each blank with exactly one identifier, operator, or constant. As always, for full credit you should use previously defined functions wherever appropriate.

```python
def fill_customer_record(RWC: Customer, all_calls: [Call]) -> Customer:
    """ """RWC" stands for "record without calls":  It's quicker to write on the exam.
    Return a customer record with that customer's outgoing and incoming calls filled in.
    """
    outgoing_call_list = ____________ (____________, RWC.phone) calls_from all_calls
    incoming_call_list = ____________ (____________, RWC.phone) calls_to all_calls
    return Customer(RWC.____________, RWC.____________, ____________.____________,
                    outgoing_call_list, incoming_call_list)
```

(b) (6 points) Suppose we have (i) the functions and namedtuples described above in this exam, (ii) the variable all_calls that contains a list of Calls containing every call made in the last year, and (iii) the variable terrorist_phones that contains ['7778889999', '6667778888', '5556667777'], representing three phone numbers of known terrorists.

Which of the following is an accurate statement? Circle one or more of A, B, C, D, E, or F; more than one may be correct.

A. Each Call in all_calls occurs twice in the list of Customers constructed from all_calls: once on the caller's outgoing list and once on the recipient's incoming list.  **YES**

B. On a given Customer's outgoing call list, every Call's num_from field is the same.  **YES**

C. On a given Customer's incoming call list, every Call's num_from field is the same.  **NO**

D. We can use calls_to_any(all_calls, terrorist_phones) to get a list of all the calls made to the terrorists' phone numbers.  **YES**

E. total_call_time(all_calls, '7778889999') gives us the number of seconds the suspected terrorist has spent on the phone.  **NO**

F. total_call_time(calls_to(all_calls, '8189990000')) gives us the number of seconds Mary Brown has spent on the phone with people who called her.  **YES**
(c) (5 points) Complete the definition of the function below, consistent with its header, docstring comment, and assertions, by filling each blank with exactly one identifier, operator, or constant.

```python
def terrorist_talk_time(c: Customer, bad_phones: [str]) -> int:
    """ Return the number of seconds this customer spent talking to terrorists on the specified list of phone numbers."
    ANSWER: total_call_time  calls_to_any  outgoing  //  total_call_time  calls_from_any  incoming
    seconds_outgoing = ____________(____________(c.____________, bad_phones))
    seconds_incoming = ____________(____________(c.____________, bad_phones))
    return ____________ + ____________
```

```python
assert terrorist_talk_time(p2, ['8189990000']) == 200
```

(d) (4 points) Suppose we complete our customer list as shown below.

```python
p1 = fill_customer_record(p1, all_calls)
p2 = fill_customer_record(p2, all_calls)
p3 = fill_customer_record(p3, all_calls)
p4 = fill_customer_record(p4, all_calls)
customer_list = [p1, p2, p3, p4]
```

Indicate the data type of each of the following expressions by selecting one item from the provided list.

A. ![Choice of data types here]

B. ![Choice of data types here]

C. ![Choice of data types here]

D. ![Choice of data types here]

E. ![Choice of data types here]

F. ![Choice of data types here]

G. ![Choice of data types here]

H. ![Choice of data types here]
Problem 5  (3 points) **Topic: Coding with boolean expressions**

Each of the three code segments below could be rewritten to have the same meaning in less code. Rewrite each segment, primarily by removing unnecessary code as discussed in class and on the lab assignments, while preserving the meaning. Just make your changes on the code below.

(a)
```python
def is_positive(num: int) -> bool:
    """ Return True if the parameter is a positive number and False otherwise
    """
    if num > 0:
        return True
    else:
        return False

    return num > 0
```

(b)
```python
if is_positive(23) == True:
    print('Positive')
else:
    print('Not positive')
if is_positive(23):
    print('Positive')
else:
    print('Not positive')
```

(c)
```python
assert is_positive(18) == True
assert is_positive(18)
```

---

When you’re done, please:

- Gather up all your stuff.
- Take your stuff and your exam down to the front of the room.
- Turn in your exam; show your ID if asked.
- Exit by the doors at the front of the room. Don't go back or disturb students still taking the test.
