Motivation

э

Challenge

- Resource Constraint
 - E.g., Limited network bandwidth, CPU.
- Implication: only a subset of sensors can be probed at a given time.
- Which sensors to probe and when.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Raking the Benefit from a Probe

Certain frames are more important than others from application perspective, which is determined by a Benefit Function (BF).

- Application 1: Real-Time building occupancy. BF = frame without presence ranked lower than all others.
- Application 2: Real-Time person location monitoring. BF = frontal image ranked higher.
- Application 3: Alert potential stolen items BF = person with back-bag ranked higher.

(a) No Presence

(b) Carrying a Bag

・ コット (雪) (小田) (コット 日)

Architecture

Two possible architectures:

- Push: Perform processing at sensor and send frame to server.
- ▶ Pull: Based on global system view, select where to probe.
- We follow the pull model for the following reasons:
 - 1. BF functions in general are complicated.
 - 2. Push is not adequate for a real-time application.

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

The Problem Statement

- Let $S_1, ..., S_n$ be *n* sensors.
- Let benefit function (BF) be an application-dependent function based on which probes can be ranked.
- Let cost function (CF) be the cost of a probe plan

Specify a probe schedule that maximizes application benefit (BF) without exceeding a cost (CF) limit.

The Problem Statement

Assumptions

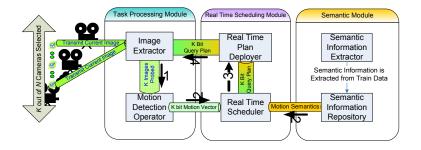

(d) BF=0, CF=1 (e) BF=1, CF=1 (f) BF=1, CF=1 (g) BF=1, CF=1

- While the framework is more general, in the paper we make two simplifications:
 - (**BF**)=1 if frame contains motion, 0 otherwise.
 - (CF)=1 if sensor probed, 0 otherwise.
- ► Under assumptions: specify a probe schedule that maximizes BF(plan) while CF(plan) ≤ k

Framework

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

The approach we adopt is to exploit semantics

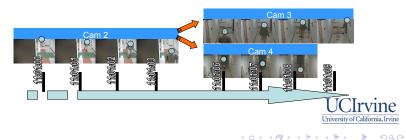

1. Apriori probability of where motion is more likely to initiate.

► 2. Self correlation of camera stream over time.

► 3. Cross Correlations over time between cameras.

Key Contributions and Challenges

- A Probabilistic semantic model for unscripted human activity.
- Predicting system state based on constrained, partial current state.
- ► 3. A fast and light weight real-time scheduler.
 - A delayed probe will miss the action.

Deterministic Alternatives

- 1. **RR** A based line algorithm, Round Robin.
- 2. **RR + Stay** Perform RR, Stay as long as motion is detected.
- 3. **RR + Stay + Go to Nearest Neighbor** Perform RR, Stay as long as motion is detected when it ends, wait (60 time units) to probe motion at nearest neighbor.
- 1. Not trivial to do better than RR+Stay, following a deterministic algorithm.

Evaluation Setup

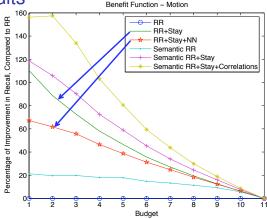

- We evaluated our algorithms on a network of 11 cameras distributed on two floors in the CS building at UC Irvine.
- The Data we collected was over a period of two weeks (the first and second weeks of the Spring quarter).
- All cameras were located in hallways.
- We then used the first week to train for optimal collection of the other week.

Some Results

- "RR+Stay+NN" performed much worse than "RR+Stay". an ad-hoc approach will prove to perform much worse than a simple alternative("RR+Stay").
- The probabilistic approach "Semantic RR" proved to work better then RR but worse than all other semantic alternatives.

Offline: from train data,compute for each sensor:

cases with motion cases with or without motion

 Online: Regardless of the actual probes, choose k nodes based on probability distribution.

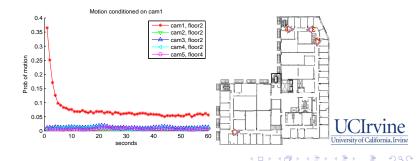

Semantic RR+Stay

We assume a *Hidden Markov Model* (HMM) of sensor states and observations.

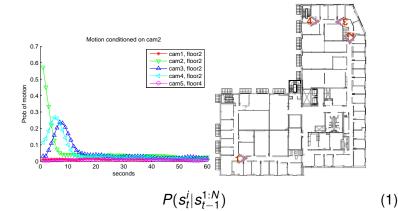

Offline: from train data, compute for each sensor:

 $P(s_t|s_{t-1})$

Online: Based on the actual probes, dynamically compute probabilities for the next time unit and choose k nodes based on probability distribution.

We would like to capture interactions between N cameras:

Superscripts denote cameras, subscripts - time.

Exponential Blowup:

The conditional probability table has 2^N entries.

Making it Scale

We assume that people move independently throughout our camera network.

- We want to intuitively "add" such probabilities across i to compute P(sⁱ_t).
- The transition model now simplifies to:

$$P(s_t^i | s_{t-1}^{1:N}) = 1 - \prod_{j=1}^N (1 - \alpha_{ij} s_{t-1}^j)$$
(2)

- 1. α_{ij} the probability that a person seen at camera *i* moves to camera *j* in the next timestep.
- 2. The above model is usually refereed to as a noisy-OR model.

The above model has $O(N^2)$ parameters - scales.

(日) (日) (日) (日) (日) (日) (日)

Again, a native implementation of P(sⁱ_{t+1}|s^{1:N}_{(t-M):t}) - exponential.

With similar reasoning, the transition model simplifies to:

$$P(s_t^i|s_{(t-M):(t-1)}^{1:N}) = 1 - \prod_{o=1}^M \prod_{j=1}^N (1 - \alpha_{ij}^o s_{t-o}^j)$$
(3)

where α_{ij}^{o} - the probability that a person in camera *i* moves to camera *j*, *o* timesteps later.

The above model has $O(M * N^2)$ parameters - scales.

(日) (日) (日) (日) (日) (日) (日)

The M^{th} -Order model states that if there is no motion activity in any camera in the past M-seconds, there can be no motion in any camera currently.

- To overcome this limitation, we allow for a probability α_i that a person will spontaneously appear at camera i this is equivalent to a *leaky* noisy OR.
- We add in $(1 \alpha_i)$ as an extra term:

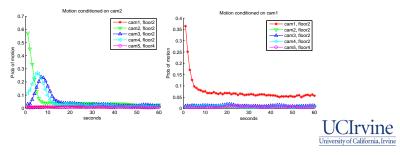

$$P(s_t^i|s_{(t-M):(t-1)}^{1:N}) = 1 - (1 - \alpha_i) * \prod_{o=1}^M \prod_{j=1}^N (1 - \alpha_{ij}^o s_{t-o}^j)$$
(4)

Implementation

Further optimization:

- We observe that most of the α^o_{ij} dependencies are weak (far-away cameras do not effect each other).
- We zero out the α_{ii}^o values below some threshold.
- In our case, thresholding on 0.05 reduced table from 1815 to 165 entries.

Implementation

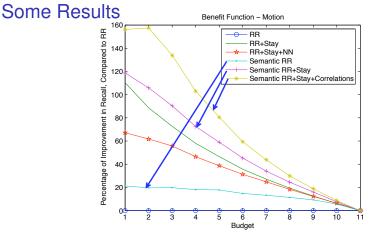

result

While experimenting we identified two pitfalls:

- 1. First we choose to probe based on **sampling**, as opposed to probing based on the order of probabilities (high to low).
- 2. The second relates to the history table, only motion probed should be used for prediction.
 - When predicting based on probability for motion -

	plan	$ C_{10} $	C_{10}	C_9	C_{10}	C_{10}	C_9	C_9	C_9	
	Cam9 Projected Prob.	0.11	0.26	0.33	0.51	0.66	0.65	0.65	0.67	
	Cam10 Projected Prob.	0.45	0.66	0.69	0.79	0.875	0.88	0.9	0.916	
	time	1	2	3	4	5	6	7	8	
	result	+	+	-	+	+	-	-	-	
When basing decision only on probed motion -										
	plan	C ₁ 0	C_{10}	C_9	C_{10}	C_{10}	C_9	C_9	C_5	
	Cam9 Projected Prob.	0.11	0.21	0.25	0.34	0.42	0.43	0.41	0.38	
	Cam10 Projected Prob.	0.45	0.65	0.56	0.71	0.8	0.67	0.63	0.6	
	time	1	2	3	4	5	6	7	8	

- With a budget of 1, our last semantic algorithm achieved over 150%(!) improvement over RR.
- With budget of 50%, the last semantic algorithm achieves about 90% recall (compared to about 50% of RR).

University of California, Irvine

イロト イポト イヨト イヨト

Demo.

Summary

- We designed and implemented a fully functional system using available off-the-shelf cameras to learn motion semantics.
- Our semantic based algorithm that takes into account all available semantic information proves that even under significant resource constraints, we can detect a very large number of events.
- The scheduling algorithm is very light weight and is suitable for a real-time application.

Outlook

• Experimenting with other **Benefit Functions**.

- Instead of 0/1 no motion/motion.
- Take into account different Cost Functions.
 - Probe in low/high resolution.
- Updating the Semantic Model while the system is in operation.
 - Relates to a problem addressed by the database communitee: estimating query selectivity based on the actual query results.
