Rina Dechter

Identification of Causal Effect The Back-Door Criterion

Primer chapter 3, Causality 1.3, 3.1, 3.2

Winter 2023

Outline (chapter 3)

- The semantic of Intervention in SCM, the do operators
- How to determine P(Y|do(x)) given an SCM
- The back door criterion and the adjustment formula
- Identifiability

Winter 2023

Target: to Determine the Effect of Interventions

- "Correlation is no causation", e.g., Increasing ice-cream sales is correlated with more crime, still selling more ice-cream will not cause more violence. Hot weather is a cause for both.
- Randomized controlled experiments are used to determine causation: all factors except a selected one of interest are kept static or random. So the outcome can only be influenced by the selected factor.
- Randomized experiments are often not feasible (we cannot randomize the weather), so how can we determine cause for wildfire?
- Observational studies must be used. But how we untangle correlation from causation?

Winter 2023

Harvard 80 years study on happiness

Harvard 80 years study

A paper in 2010

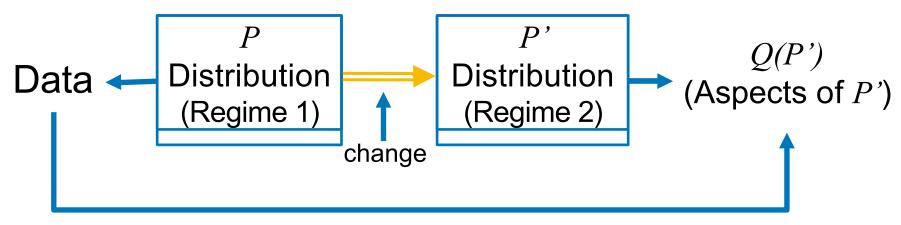

Keywords: social functioning, aging, marital satisfaction, health, happiness

Abstract:

This study examined day-to-day links between perceived health and happiness and between time spent with others and happiness in 47 older adult couples over an 8-day period. Marital satisfaction and time spent with others were explored as potential moderators of links between health and happiness. For both men and women, hierarchical linear modeling revealed daily links between more time spent with others and greater happiness. Daily links between time spent with one's partner and happiness were strongly moderated by marital satisfaction. For both men and women, marital satisfaction buffered day-to-day links between poorer perceived health and a decline in happiness, but time spent with others did not. This study provides support for the role of marital satisfaction in protecting older adults' happiness from daily fluctuations in perceived physical health, and for the influence of social connections in promoting happiness in the lives of older adults. Causal Inference — Connecting Different Worlds

Inference

What happens when *P* changes?

e.g., Infer whether less people would get cancer if we ban smoking.

$$Q = P(Cancer = true \mid do(Smoking = no))$$
 Not an aspect of P .

The Challenge of Causal Inference

Z: age, sex

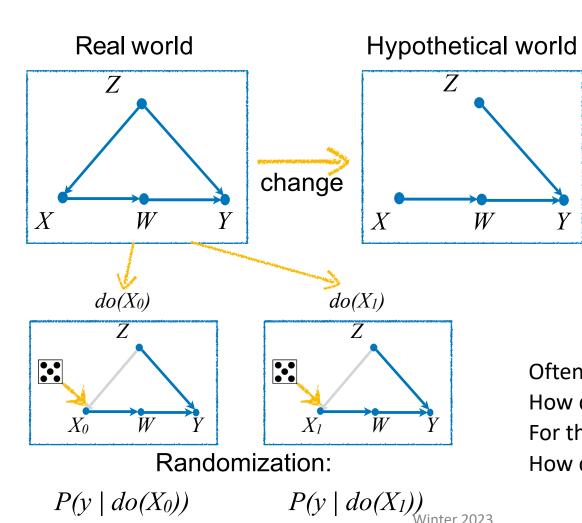

X: action

W: mediator

Y: outcome

- Goal: how much Y changes with X if we vary X between two different constants free of the influence of Z.
- These variations are called causal effects!

Method for Computing Causal Effects: Randomized Experiments

Z: age, sex

X: action

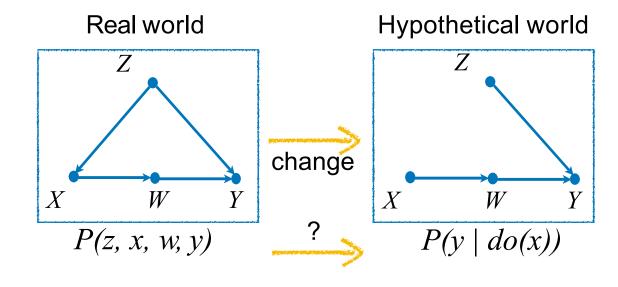

W: mediator

Y: outcome

Often we cannot do this:

How do we force people to smoke (and wait 20 years For them to die or not)

How can we change cholesterol levels...

Z: age, sex

X: action

W: mediator

Y: outcome

Questions:

* What is the relationship between P(z, x, w, y) and $P(y \mid do(x))$?

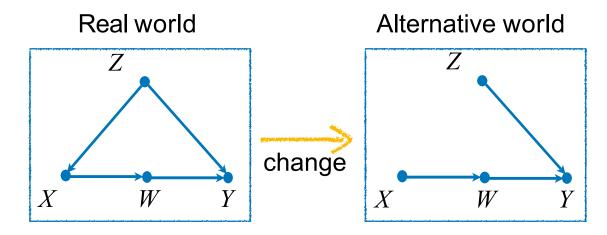

* Is $P(y \mid do(x)) = P(y \mid x)$?

Causal Effects (formal)

Causal Effect (Def. 3.2.1 [C]):

Given two disjoint sets of variables, X and Y, the causal effect of X on Y, denoted as $P(y \mid do(x))$, is a function from X to the space of probability distributions of Y.

For each realization x of X, $P(y \mid do(x))$ gives the probability Y = y induced by deleting from the model all equations corresponding to variables in X and substituting X = x in the remaining equations.

Z: age, sex

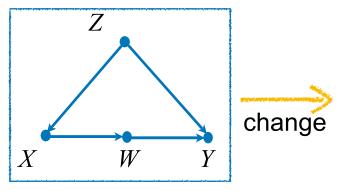

X: action

W: mediator

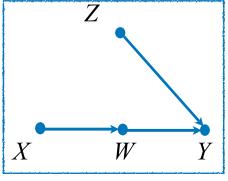

Y: outcome

$$M = \begin{cases} Z = f_{Z}(u_{z}) \\ X = f_{X}(z, u_{x}) \\ W = f_{W}(x, u_{w}) \\ Y = f_{Y}(w, z, u_{y}) \end{cases} \qquad M_{X} = \begin{cases} Z = f_{Z}(u_{z}) \\ X = f_{X}(z, u_{x}) \\ W = f_{W}(x, u_{w}) \\ Y = f_{Y}(w, z, u_{y}) \end{cases}$$

Real world

Alternative world

Z: age, sex

X: action

W: mediator

Y: outcome

$$P(v) =$$

$$P(z) \times P(x \mid z) \times P(w \mid x) \times P(y \mid w, z)$$

$$do(X=x)$$

$$P_x(v) =$$

$$P(z) \times P(x|z) \times equal to 1 in Mx P(w|x) \times P(y|w,z)$$

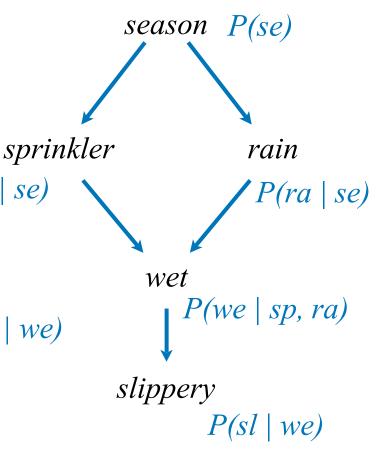

Outline (chapter 3)

- The semantic of Intervention in SCM, the do operators
- How to determine P(Y|do(x)) given an SCM
- The back door criterion and the adjustment formula
- Identifiability

Consider a distribution over the variables: season, sprinkler, rain, wet, and *slippery*; and the causal graph:

This distribution decomposes as

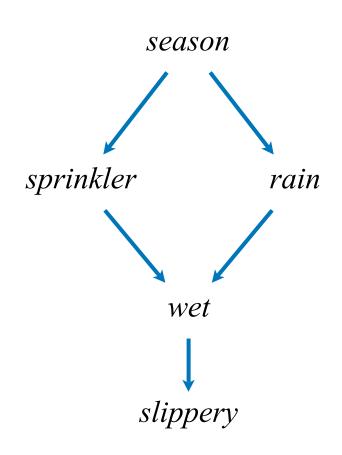

$$P(\mathbf{v}) = P(\mathbf{s}e)P(\mathbf{s}p \mid \mathbf{s}e)P(\mathbf{r}a \mid \mathbf{s}e)P(\mathbf{w}e \mid \mathbf{s}p, \mathbf{r}a)P(\mathbf{s}l \mid \mathbf{w}e)$$

Queries:

$$Q_1 = P(wet \mid Sprinkler = on)$$

$$Q_2 = P(wet \mid do(Sprinkler = on))$$

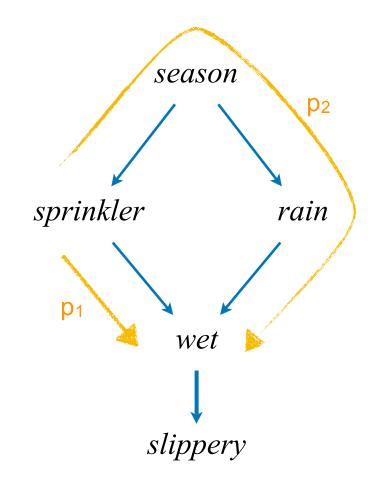

Queries:

$$Q_1 = P(wet \mid Sprinkler = on)$$

= $P(p_1) + P(p_2)$

$$Q_2 = P(wet \mid do(Sprinkler = on))$$

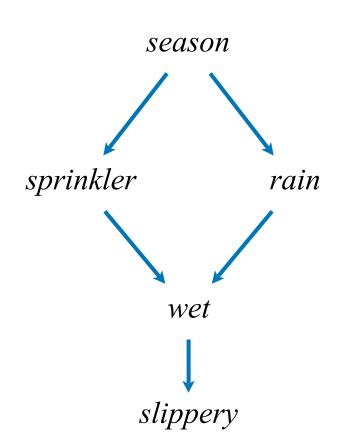

Queries:

$$Q_1 = P(wet \mid Sprinkler = on)$$

$$= \frac{\sum_{se,ra} P(we \mid Sp = on, ra) P(Sp = on \mid se) P(ra \mid se) P(se)}{\sum_{se} P(Sp = on \mid se) P(se)}$$

$$Q_2 = P(wet \mid do(Sprinkler = on))$$

You can do algorithm bucket elimination to infer Q1.

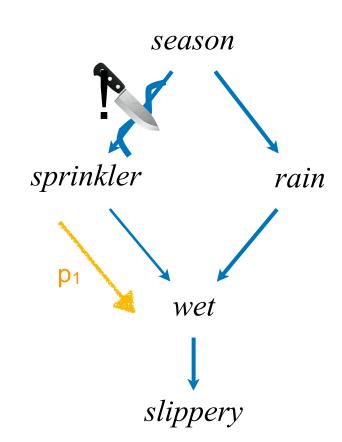

Queries:

$$Q_1 = P(wet \mid Sprinkler = on)$$

$$=\frac{\sum_{se,ra}P(we\,|\,Sp=on,ra)P(Sp=on\,|\,se)P(ra\,|\,se)P(se)}{\sum_{se}P(Sp=on\,|\,se)P(se)}$$

$$Q_2 = P(wet \mid do(Sprinkler = on))$$

You can do algorithm bucket elimination to infer Q2.

Queries:

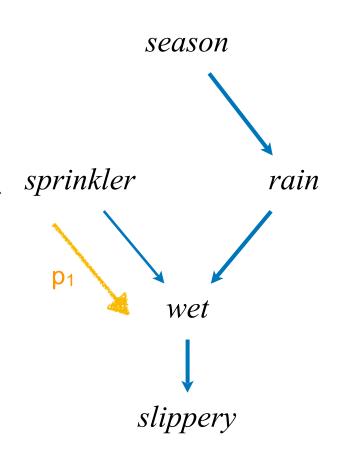

$$Q_1 = P(wet \mid Sprinkler = on)$$

$$= \frac{\sum_{se,ra} P(we \mid Sp = on, ra) P(Sp = on \mid se) P(ra \mid se) P(se)}{\sum_{se} P(Sp = on \mid se) P(se)}$$

$$Q_2 = P(wet \mid do(Sprinkler = on))$$

= $P(p_1)$

You can do algorithm bucket elimination to infer Q1.

Queries:

$$Q_1 = P(wet \mid Sprinkler = on)$$

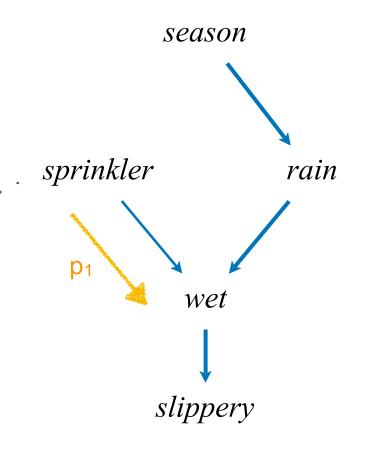

$$= \frac{\sum_{se,ra} P(we \mid Sp = on, ra) P(Sp = on \mid se) P(ra \mid se) P(se)}{\sum_{se} P(Sp = on \mid se) P(se)}$$

$$Q_2 = P(wet \mid do(Sprinkler = on))$$

$$= \frac{\sum_{se,ra} P(we \mid Sp = on, ra) P(Sp = on) P(ra \mid se) P(se)}{P(Sp = on)}$$
equal to 1

$$= \sum P(we \,|\, Sp = on, ra) P(ra \,|\, se) P(se)$$

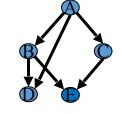

se,ra

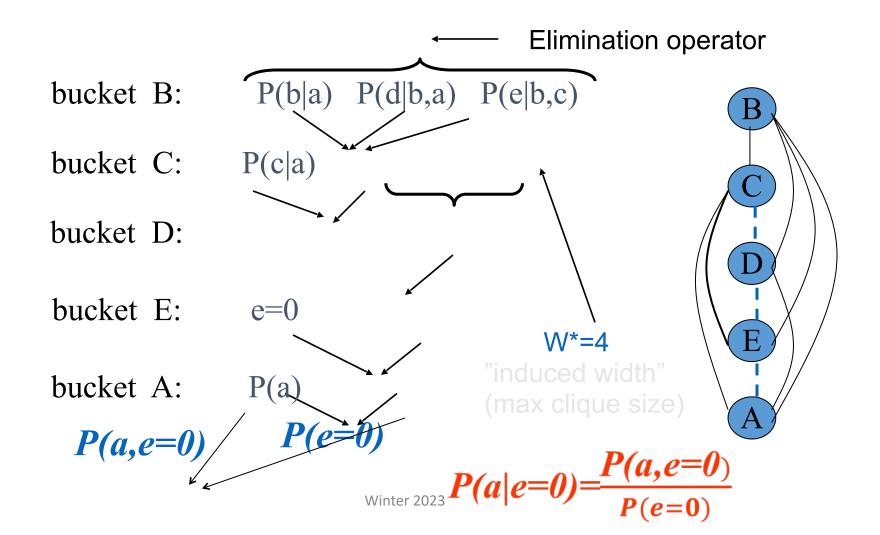

You can do algorithm bucket elimination to infer Q2.

Bucket elimination

Algorithm BE-bel (Dechter 1996)

Truncated Factorization Product (Operationalizing Interventions)

Corollary (Truncated Factorization, Manipulation Thm., G-comp.):

The distribution generated by an intervention do(X=x) (in a Markovian model M) is given by the truncated factorization:

$$P(\mathbf{v} \mid do(\mathbf{x})) = \prod_{\{V_i \in \mathbf{V} \setminus \mathbf{X}\}} P(v_i \mid pa_i) \Big|_{\mathbf{X} = \mathbf{x}}$$

Truncated Factorization Formula

The truncated product,

$$P(\mathbf{v} | do(\mathbf{x})) = \prod_{\{V_i \in \mathbf{V} \setminus \mathbf{X}\}} P(v_i | pa_i) \bigg|_{\mathbf{X} = \mathbf{x}}$$

can be rewritten as:

$$P(\mathbf{v} | do(\mathbf{x})) = \frac{P(\mathbf{v})}{P(\mathbf{x} | pa_{\mathbf{x}})} \bigg|_{\mathbf{X} = \mathbf{x}}$$

Also equivalent to:

$$P(\mathbf{v} \mid do(\mathbf{x})) = P(\mathbf{v} \mid \mathbf{x}, pa_{\mathbf{x}}) P(pa_{\mathbf{x}}) \Big|_{\mathbf{X} = \mathbf{x}}$$

The transformation between the observation and interventional distributions can be seen as a re-weighing process.

23

Intervention vs. Conditioning, The Ice-Cream Story

Conditioning P(Y=y|X=x)
Intervening P(Y=y| do(X=x))

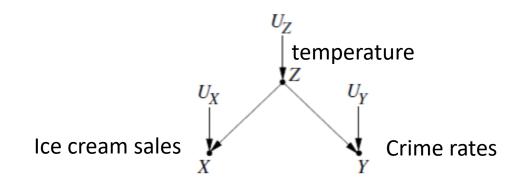

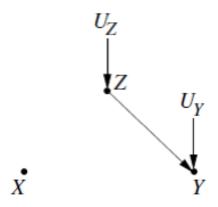

Figure 3.1: A graphical model representing the relationship between temperature (Z), ice cream sales (X), and crime rates (Y)

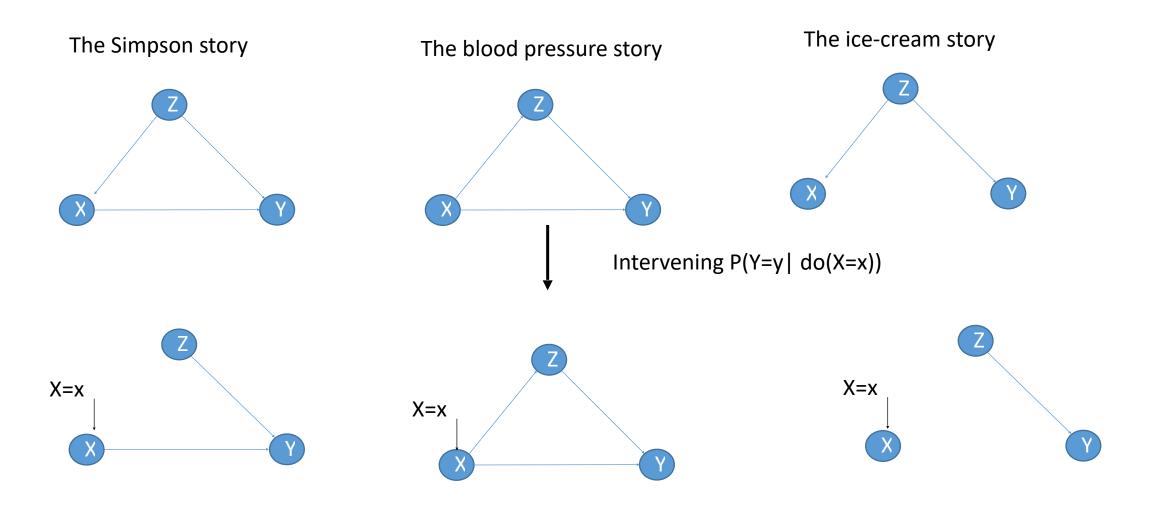

When we intervene to fix a value of a variable, We curtail the natural tendencies of the variable to vary In response to other variables in nature.

- This corresponds to a surgery of the model
- i.e. varying Z will not affect X
- Intervention depends on the structure of the graph.

Figure 3.2: A graphical model representing an intervention on the model in Figure 3.1 that lowers ice cream sales

Intervention vs Conditioning, The Surgery Operation

Conditioning P(Y=y|X=x)

Intervention vs. Conditioning...

In notation, we distinguish between cases where a variable X takes a value x naturally and cases where we fix X=x by denoting the latter do(X=x). So P(Y=y|X=x) is the probability that Y=y conditional on finding X=x, while P(Y=y|do(X=x)) is the probability that Y=y when we intervene to make X=x. In the distributional terminology, P(Y=y|X=x) reflects the population distribution of Y among individuals whose X value is x. On the other hand, P(Y=y|do(X=x)) represents the population distribution of Y if everyone in the population had their X value fixed at x. We similarly write P(Y=y|do(X=x),Z=z) to denote the conditional probability of Y=y, given Z=z, in the distribution created by the intervention do(X=x).

Do operation and graph surgery can help determine causal effect

We make an assumption that intervention has no side-effect. Namely, assigning a variable by intervention does not affect other variables in a direct way.

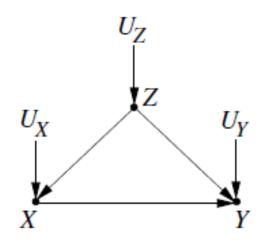

The Adjustment Formula

To find out how effective the drug is in the population, we imagine a hypothetical intervention by which we administer the drug uniformly to the entire population and compare the recovery rate to what would obtain under the complementary intervention, where we prevent everyone from using the drug.

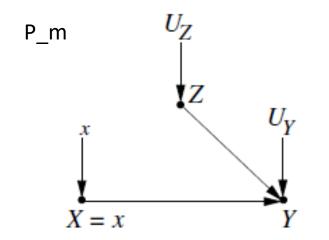

We want to estimate the "causal effect difference," or "average causal effect" (ACE).

$$P(Y = 1|do(X = 1)) - P(Y = 1|do(X = 0))$$
 (3.1)

Definition of Intervention and Graph Surgery: The Adjustment Formula

- We simulate the intervention in the form of a graph surgery.
- The causal effect P(Y = y | do(X = x)) equals to the conditional probability $P_m(Y = y | X = x)$ that prevails in the manipulated model of the figure below

Important: the random functions for Z and Y remain invariant

$$P_m(Y=y|Z=z,X=x)=P(Y=y|Z=z,X=x)\quad \text{and}\quad P_m(Z=z)=P(Z=z)$$

The Adjustment Formula

$$P(Y = y|do(X = x)$$

$$= P_m(Y = y|X = x)$$
 (by definition) (3.2)

$$= \sum_{z} P_m(Y = y | X = x, Z = z) P_m(Z = z | X = x)$$
 (3.3)

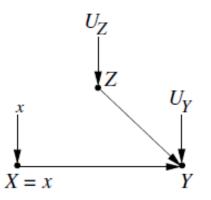

$$= \sum_{z} P_m(Y = y | X = x, Z = z) P_m(Z = z)$$
(3.4)

Equation (3.3) is obtained from Bayes' rule by conditioning on and summing over all values of Z = z (as in Eq. (1.19)), while (Eq. 3.4) makes use of the independence of Z and X in the modified model.

Finally, using the invariance relations, we obtain a formula for the causal effect, in terms of preintervention probabilities:

$$P(Y = y|do(X = x)) = \sum_{z} P(Y = y|X = x, Z = z)P(Z = z)$$
 (3.5)

Equation (3.5) is called the *adjustment formula* and as you can see, it computes the association between X and Y for each value z of Z, then averages over those values. This procedure is referred to as "adjusting for Z" or "controlling for Z."

The Adjustment Formula (in the Simpson story)

$$P(Y = y|do(X = x)) = \sum_{z} P(Y = y|X = x, Z = z)P(Z = z)$$
 (3.5)

The right hand-side can be estimated from the data since it has only conditional probabilities.

If we had a randomized controlled experiments on X (taking the drug) we would not need adjustment Because the data is already generated from the manipulated distribution. Namely it will yield P(Y=y|do(x)) From the data of the randomized experiment.

In practice adjustment is sometime used in randomized experiments to reduce sampling variations (Cox 1958). (This means: If the input is sampled from the **intervened upon** joint distribution over X,Y and Z we can estimate the P(y|x) directly. Or, we can first estimate P(y|x,z) and also P(z) and perform the summation.)

In the Simpson example:

Table 1.1 Results of a study into a new drug, with gender taken into account

	Drug	No drug
Men	81 out of 87 recovered (93%)	234 out of 270 recovered (87%)
Women	192 out of 263 recovered (73%)	55 out of 80 recovered (69%)
Combined data	273 out of 350 recovered (78%)	289 out of 350 recovered (83%)

$$P(Y = 1|do(X = 1)) = P(Y = 1|X = 1, Z = 1)P(Z = 1) + P(Y = 1|X = 1, Z = 0)P(Z = 0)$$

Substituting the figures given in Table 1.1 we obtain

$$P(Y=1|do(X=1)) = \frac{0.93(87+270)}{700} + \frac{0.73(263+80)}{700} = 0.832$$

while, similarly,

$$P(Y=1|do(X=0)) = \frac{0.87(87+270)}{700} + \frac{0.69(263+80)}{700} = 0.7818$$

 U_{Z} Z U_{Y} X = x

We get that the Average Causal Effect (ACE):

$$ACE = P(Y = 1|do(X = 1)) - P(Y = 1|do(X = 0)) = 0.832 - 0.7818 = 0.0502$$

A more informal interpretation of ACE is that it is the difference in the fraction of the population that would recover if everyone took the drug compared to when no one takes the drug.

The Blood Pressure Example

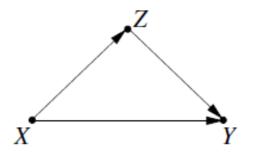

Figure 3.5: A graphical model representing the effects of a new drug, with X representing drug usage, Y representing recovery, and Z representing blood pressure (measured at the end of the study). Exogenous variables are not shown in the graph, implying that they are mutually independent

$$P(Y=y \mid do(X=x) = ?)$$
 Here the "surgery on X changes nothing. So,

This means that no surgery is required; the conditions under which data were obtained were such that treatment was assigned "as if randomized." If there was a factor that would make subjects prefer or reject treatment, such a factor should show up in the model; the absence of such a factor gives us the license to treat X as a randomized treatment.

$$P(Y = y|do(X = x)) = P(Y = y|X = x),$$

To Adjust or not to Adjust?

Rule 1 (The Causal Effect Rule) Given a graph G in which a set of variables PA are designated as the parents of X, the causal effect of X on Y is given by

$$P(Y = y|do(X = x) = \sum_{z} P(Y = y|X = x, PA = z)P(PA = z)$$
(3.6)

Where z ranges over all the combinations of values that the variables that PA take.

So, the causal graph helps determine the parents PA!

But, in many cases some of the parents are unobserved so we cannot perform the calculation.

Luckily we can often adjust for other variables substituting for the unmeasured variables in PA(X), and this Can be decided via the graph.

Multiple Interventions, the Truncated Product Rule

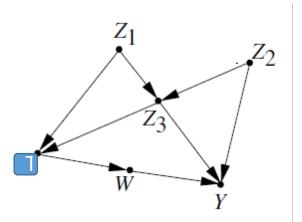

Often we have multiple interventions that may not correspond to disconnected variables. We will use the product decomposition. We write **the product truncated formula**

$$P(x_1,x_2,\dots,x_n|do(x)) = \prod_i P(x_i|pa_i) \qquad \text{ for all i with X_i not in X.}$$

$$P(z_1, z_2, w, y|do(T = t, Z_3 = z_3)) = P(z_1)P(z_2)P(w|t)P(y|w, z_3, z_2)$$

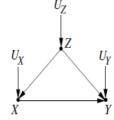

where we have deleted the factors $P(t|z_1, z_3)$ and $P(z_3|z_1, z_2)$ from the product.

Example:

Multiple Interventions and the Truncated Product Rule

preintervention distribution in the model of Figure 3.3 is given by

$$P(x, y, z) = P(z)P(x|z)P(y|x, z)$$

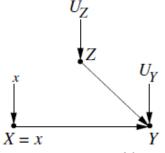

Figure 3.3: A graphical model representing the effects of a new drug, with Z representing gender, X standing for drug usage, and Y standing for recovery

whereas the postintervention distribution, governed by the model of Figure 3.4 is given by the product

$$P(z, y|do(x)) = P_m(z)P_m(y|x, z) = P(z)P(y|x, z)$$
(3.9)

with the factor P(x|z) purged from the product, since X becomes parentless as it is fixed at X = x. This coincides with the adjustment formula, because to evaluate P(y|do(x)) we need to marginalize (or sum) over z, which gives

$$P(y|do(x)) = \sum_{z} P(z)P(y|x,z)$$

Outline (chapter 3)

- The semantic of Intervention in SCM, the do operators
- How to determine P(Y | do(x)) given an SCM
- The identification problem
- The back door criterion and the adjustment formula

The Identification Problem

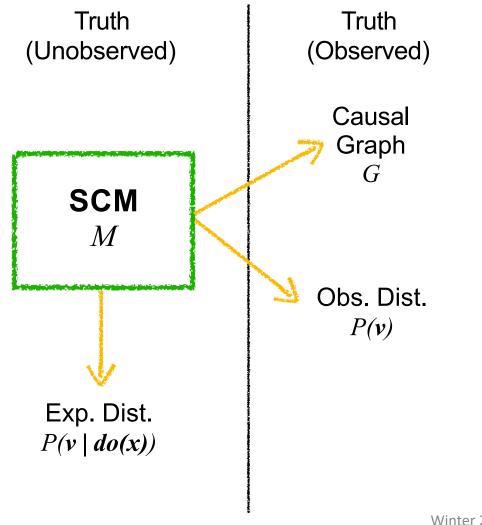

Causal Effect Identifiability (Def. 3.2.2)

The causal effect of X on Y is said to be identifiable from a causal diagram G if the quantity $P(y \mid do(x))$ can be computed uniquely from a positive probability of the observed variables.

That is, if for every pair of models M_1 and M_2 inducing G, $P_{M_1}(\mathbf{y} \mid do(\mathbf{x})) = P_{M_2}(\mathbf{y} \mid do(\mathbf{x}))$, whenever $P_{M_1}(\mathbf{v}) = P_{M_2}(\mathbf{v}) > 0$.

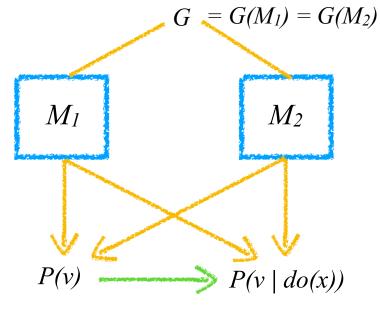

37

The Identification Problem (II)

Causal Inference

For any two SCMs M_1 , M_2 ,

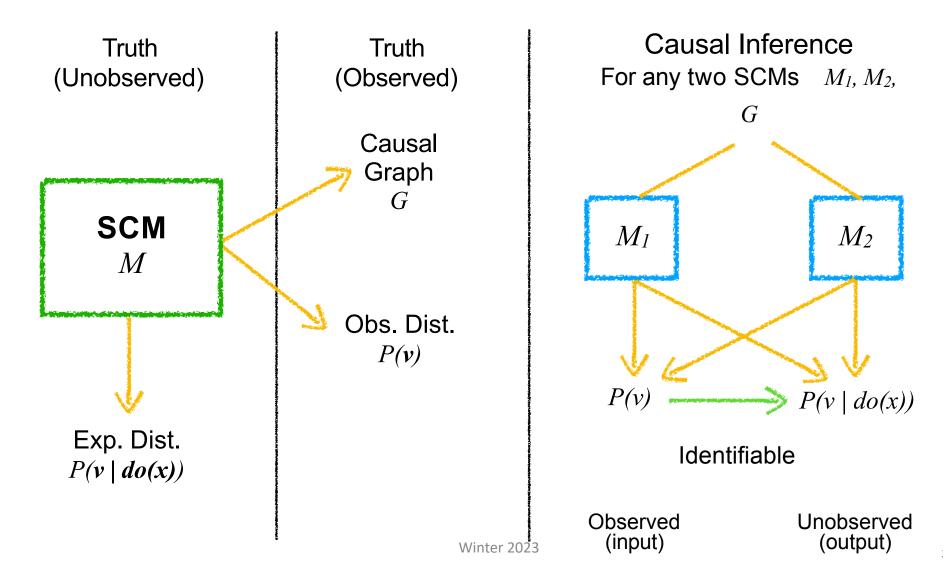

$$(P_{MI}(v) = P_{M2}(v)) \qquad (P_{MI}(y|do(x)))$$
Observed (input)
$$= P_{M2}(y|do(x))$$

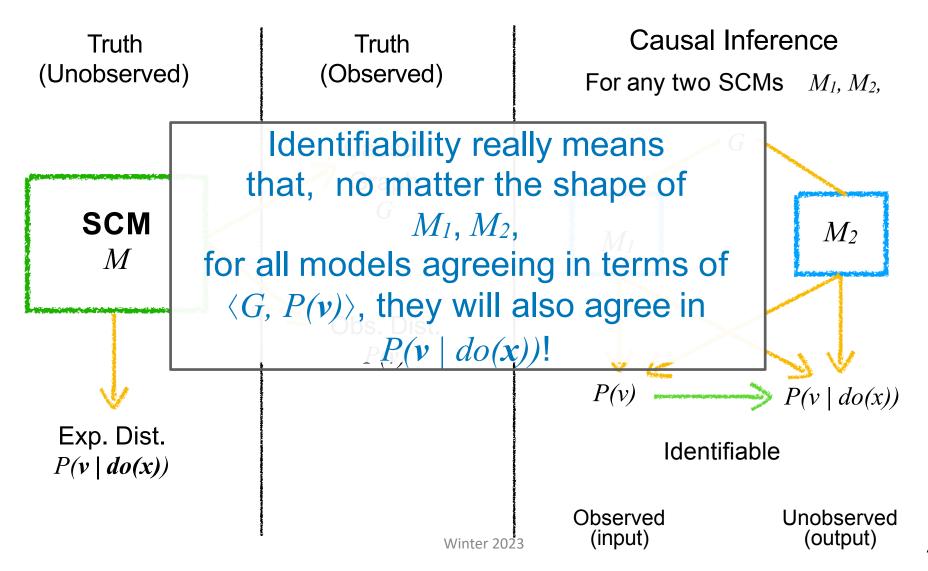

Unobserved (output)

Winter 2023

The Identification Problem (II)

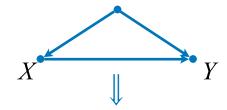

The Identification Problem (II)

Example. Identifiable Effect

 Consider any two pair of models compatible with the following graph and the same observational distribution P(v):

Z

$$X$$
 \downarrow Y

$$P(\mathbf{v}) = P(z)P(x|z)P(y|x,z)$$

$$M^{(1)} = \begin{cases} Z \leftarrow f_z^{(1)}(u_z) & P(v|do(x)) = P(z)P(y|x,z) \\ X \leftarrow f_x^{(1)}(z, u_x) & Z \leftarrow X \\ Y \leftarrow f_y^{(1)}(x, z, u_y) & do(x) \end{cases} M^{(1)} = \begin{cases} Z \leftarrow f_z^{(1)}(u_z) \\ X \leftarrow x \\ Y \leftarrow f_y^{(1)}(x, z, u_y) \end{cases}$$

$$P(\mathbf{v}|do(x)) = P(z)P(y|x,z)$$

$$M^{(1)} = \begin{cases} Z \leftarrow f_{z}^{(1)}(u) \\ X \leftarrow x \\ Y \leftarrow f_{y}^{(1)}(x,z,u_{y}) \end{cases}$$

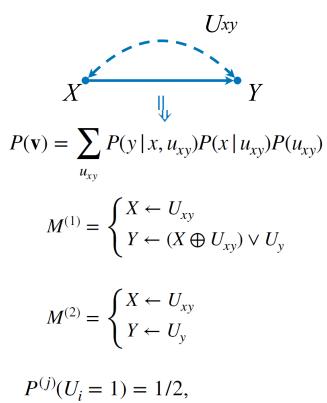

$$M^{(2)} = \begin{cases} Z \leftarrow f_{z}^{(2)}(u_{z}) \\ X \leftarrow f_{z}^{(2)}(z, u) \\ X \leftarrow f_{z}^{(2)}(z, z, u) \\ Y \leftarrow f_{y}^{(2)}(x, z, u) \end{cases} \qquad M^{(2)} = \begin{cases} Z \leftarrow f_{z}^{(2)}(u_{z}) \\ X \leftarrow x \\ Y \leftarrow f_{y}^{(2)}(x, z, u_{y}) \end{cases}$$

$$M^{(2)} = \begin{cases} Z \leftarrow f_{z}^{(2)}(u) \\ X \leftarrow x \\ Y \leftarrow f_{y}^{(2)}(x, z, u_{y}) \\ \text{Winter 2023} \end{cases}$$

 $D(y|do(y)) = \nabla D(z)D(y|x,z)$ No matter what the specific functions or P(u) are, as long as M_1 , M_2 agree in $\langle G, P(v) \rangle$, they will also agree in P(z) and P(y|x,z), hence in $P(v \mid do(x))!$

Example. Non-identifiable Effect

 Consider the pair of models compatible with the following graph G and observational distribution P(v).

$\mathbf{p}(i)(\mathbf{H} = 1)$
$P^{(j)}(U_i = 1) = 1/2,$
$i = \{x, y, xy\}, j = \{1, 2\}$

U_y	Uxv	X	<i>Y</i> (1)	Y(2)	$P(\mathbf{v}, \mathbf{u})$
0	0	0	0	0	1/8
0	1	1	0	0	1/8
1	0	0	1	1	1/8
1	1	1	1	1	1/8
0	0	0	0	0	1/8
0	1	1	0	0	1/8
1	0	0	1	1	1/8
1	1	1	1	1	1/8
			\downarrow		

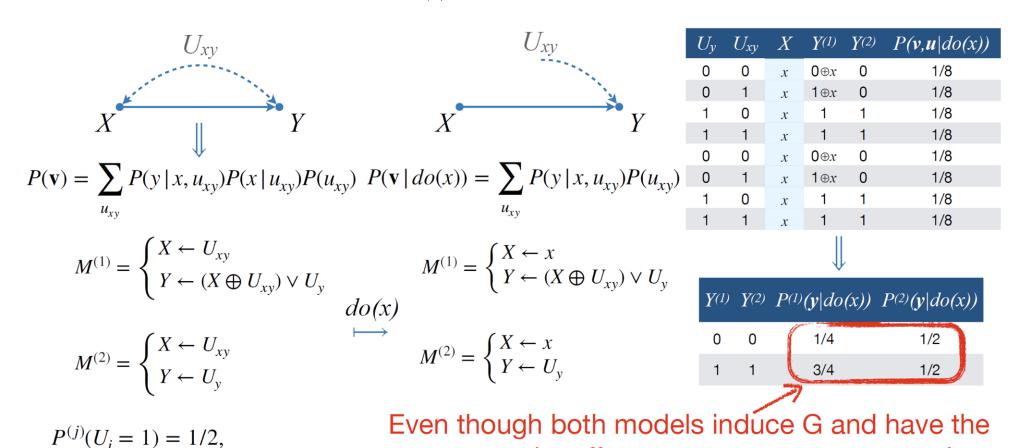

X	Y (1)	Y(2)	$P^{(1)}(\mathbf{v})$	$P^{(2)}(\mathbf{v})$
0	0	0	1/4	1/4
0	1	1	1/4	1/4
1	0	0	1/4	1/4
1	1	1	1/4	1/4
		(

They match in P(v), that is, P(1)(v) = P(2)(v)!

Example. Non-identifiable Effect

 $i = \{x, y, xy\}, j = \{1, 2\}$

• Consider the pair of models compatible with the following graph *G* and observational distribution *P*(*v*):

same P(v), the effect $P^{(1)}(y|do(x)) \neq P^{(2)}(y|do(x))!$

Let's study how to decide whether a causal effect is identifiable...

Identification in Markovian Models

Theorem. Given the causal diagram G of any Markovian model that all variables are measured, the causal effect $Q = P(y \mid do(x))$ is identifiable for every subsets of variables X and Y and is obtained from the truncated factorization, i.e.,

$$P(\mathbf{v} \mid do(\mathbf{x})) = \prod_{\{V_i \in \mathbf{V} \setminus \mathbf{X}\}} P\left(v_i \mid pa_i\right) \text{ Sum over all variables not in } X \cup Y$$

$$P(\mathbf{y} | do(\mathbf{x})) = \sum_{\mathbf{v} \setminus (\mathbf{x} \cup \mathbf{y})} \prod_{\{V_i \in \mathbf{V} \setminus \mathbf{X}\}} P(v_i | pa_i)$$

Adjustment by Direct Parents

Thm. Given a causal diagram G of any Markovian system, the causal quantity $Q = P(y \mid do(x))$ is identifiable whenever $\{X, Y, Pa_x\} \subseteq V$, that is, whenever X, Y, and all the parents of variables X are measured. The expression of Q is then obtained by adjustment for PA_x , or

$$P(\mathbf{y} | do(\mathbf{x})) = \sum_{pa_{\mathbf{x}}} P(\mathbf{y} | \mathbf{x}, pa_{\mathbf{x}}) P(pa_{\mathbf{x}})$$

Quiz: 1) derive from previous slide

2) derive for non-Markovian models

How could adjustment help in real data analysis?

(The Problem of Confounding)

Winter 2023 47

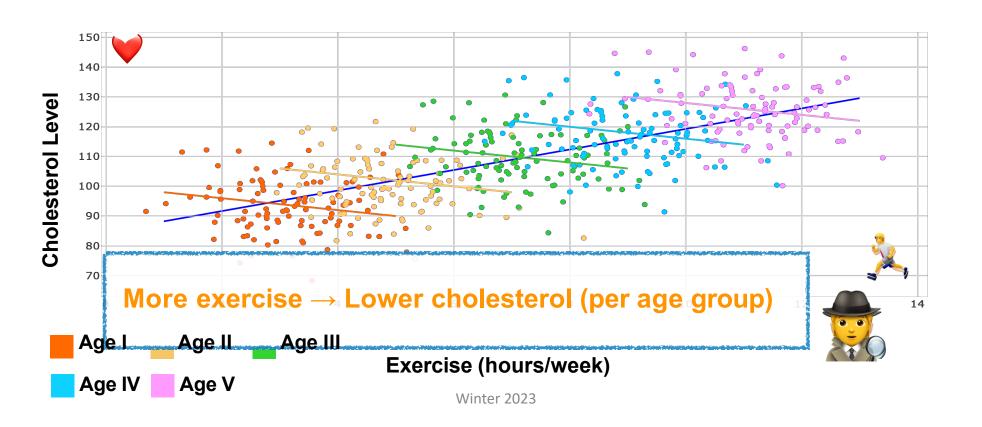

Confounding Bias

What's the causal effect of Exercise on Cholesterol? age What about $P(cholesterol \mid exercise)$? exercise cholesterol 150 140 130 **Cholesterol Level** 120 110 100 70 **Increase exercise** → increase cholesterol? **Exercise** (hours/week)

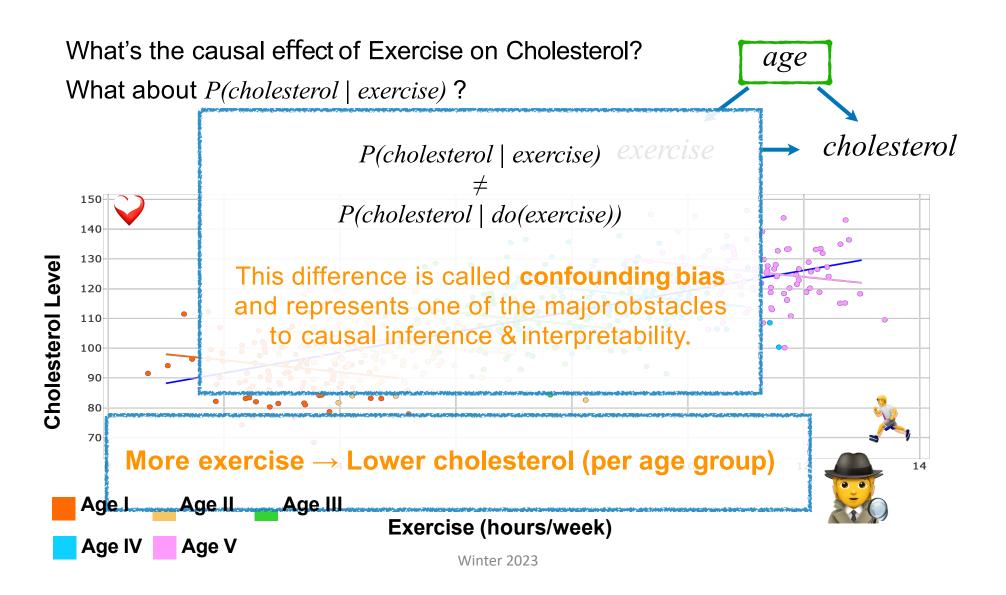

Confounding Bias

What's the causal effect of Exercise on Cholesterol?

What about $P(cholesterol \mid exercise)$? $exercise \rightarrow cholesterol$

Confounding Bias

If Season is latent, is the effect still computable?

Queries:

$$Q_2 = P(wet \mid do(Sprinkler = on))$$

$$= \frac{\sum_{se,ra} P(we \mid Sp = on, ra) P(Sp = on) P(ra \mid se) P(se)}{P(Sp = on)}$$

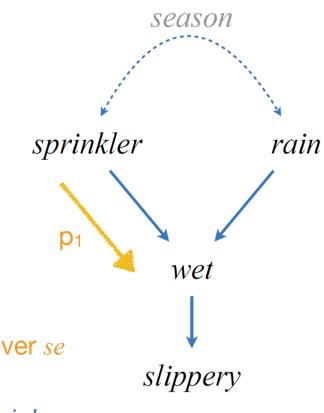

$$= \sum P(we | Sp = on, ra)P(ra | se)P(se)$$
 equal to 1

$$= \sum P(we | Sp = on, ra)P(ra, se)$$
 chain rule

$$= \sum_{ra} P(we | Sp = on, ra) \sum_{se} P(ra, se)$$
 summing over se

$$= \sum_{ra} P(we \mid Sp = on, ra)P(ra)$$

Adjustment by Rain!

If Season is latent, is the effect still computable?

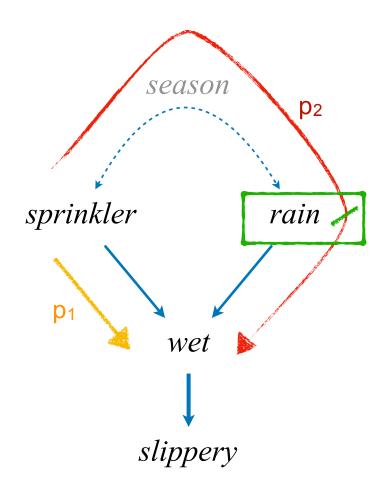

Queries:

$$Q_2 = P(wet \mid do(Sprinkler = on))$$

$$= \sum_{ra} P(we | Sp = on, ra)P(ra)$$

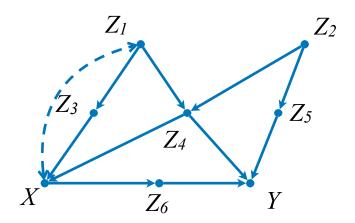

By conditioning on rain,

- p₂ (the non-causal path) is blocked, and
- p₁ (the causal path) remains unaffected!

Is Confounding Bias removable?

Goal: Find the effect of X on Y, Q = P(y|do(x)), given measurements on variables $Z_1,..., Z_k$,

where some of X parents are unobserved. How can the target quantity Q be identified if only a subset of the parents is measured?

Outline (chapter 3)

- The semantic of Intervention in SCM, the do operators
- How to determine P(Y | do(x)) given an SCM
- The identification problem
- The back door criterion and the adjustment formula

Winter 2023 54

3.3 The Backdoor Criterion

Definition 3.3.1 (The Backdoor Criterion) Given an ordered pair of variables (X,Y) in a directed acyclic graph G, a set of variables Z satisfies the backdoor criterion relative to (X,Y) if no node in Z is a descendant of X, and Z blocks every path between X and Y that contains an arrow into X.

If a set of variables Z satisfies the backdoor criterion for X and Y, then the causal effect of X on Y is given by the formula

$$P(Y=y|do(X=x)) = \sum_{z} P(Y=y|X=x,Z=z) P(Z=z)$$

Rationale:

- 1. We block all spurious paths between X and Y.
- 2. We leave all directed paths from X to Y unperturbed.
- 3. We create no new spurious paths.

The Back-door Adjustment

Theorem 3.3.2 (Back-door Adjustment)

If a set Z satisfies the bdc w.r.t the pair X, Y, the effect of X on Y is identifiable and given by:

$$P(\mathbf{y} | do(\mathbf{x})) = \sum_{\mathbf{z}} P(\mathbf{y} | \mathbf{x}, \mathbf{z}) P(\mathbf{z})$$

Back-Door Sets as Substitutes of the Direct Parents of X

back-door

rain

path

season

sprinkler

Rain satisfies the back-door criterion relative to *Sprinkler* and *Wet*:

- (i) Rain is not a descendant of Sprinkler, and (ii) Rain blocks the only back-door path from Sprinkler to Wet.
- Adjusting for the direct parents of *Sprinkler*, we have:

Direct derivation, showing it works

$$P(we \mid do(sp)) = \sum_{se} P(we \mid sp, se) P(se)$$

$$= \sum_{se,ra} P(we \mid sp, se, ra) P(ra \mid sp, se) P(se)$$

$$= \sum_{se,ra} P(we \mid sp, ra) P(ra \mid se) P(se)$$

$$= \sum_{se,ra} P(we \mid sp, ra) \sum_{se} P(ra, se) = \sum_{ra} P(we \mid sp, ra) P(ra)$$
Adjustment by Rain

Adjustment by Direct Parents

→ Back-door Adjustment

More Generally:

- (i) no node in Z is a descendent of X; and
- (ii) Z blocks every path between X and Y that contains an arrow into X.

$$\Rightarrow (X \perp Z \mid Pa_x)$$

$$\Rightarrow (Y \perp Pa_x \mid Z, X)$$

Then:

$$P(\mathbf{y} | do(\mathbf{x})) = \sum_{pa_{\mathbf{x}}} P(\mathbf{y} | \mathbf{x}, pa_{\mathbf{x}}) P(pa_{\mathbf{x}})$$

$$= \sum_{\mathbf{z}, pa_{\mathbf{x}}} P(\mathbf{y} | \mathbf{x}, pa_{\mathbf{x}}, \mathbf{z}) P(\mathbf{z} | \mathbf{x}, pa_{\mathbf{x}}) P(pa_{\mathbf{x}})$$

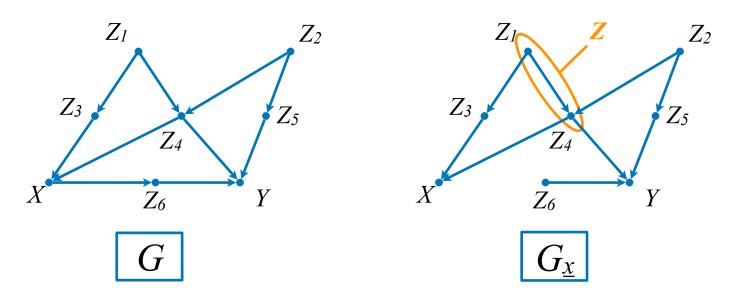

$$= \sum_{\mathbf{z}, pa_{\mathbf{x}}} P(\mathbf{y} | \mathbf{x}, \mathbf{z}) P(\mathbf{z} | pa_{\mathbf{x}}) P(pa_{\mathbf{x}})$$

$$= \sum_{\mathbf{z}} P(\mathbf{y} | \mathbf{x}, \mathbf{z}) \sum_{pa_{\mathbf{x}}} P(\mathbf{z}, pa_{\mathbf{x}}) = \sum_{\mathbf{z}} P(\mathbf{y} | \mathbf{x}, \mathbf{z}) P(\mathbf{z})$$

Adjustment by **Z** is equivalent to adjustment by direct parents whenever **Z** is bd-admissible!

How do we find these bd-sets? Graphical Condition

 $P(y \mid do(x))$ is identifiable if there is a set Z that d-separates X from Y in $G_{\underline{x}}$ (the graph G where all arrows emanating from X are removed.)

$$P(y \mid do(x)) = \sum_{z_1, z_4} P(y \mid x, z_1, z_4) P(z_1, z_4)$$

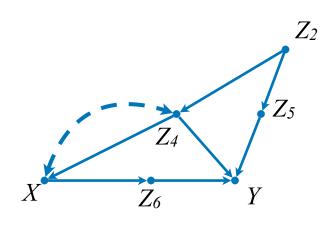

Back-door Examples

Are there admissible back-door sets (relative to *X,Y*) for the following graphs?

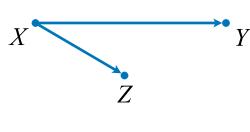

Back-door Examples

Are there admissible back-door sets (relative to X, Y) for the following graphs?

$$Z=\{Z_4, Z_2\}, \{Z_4, Z_5\}, \{Z_4, Z_5\}, \{Z_4, Z_2, Z_5\}$$

$$Z=\emptyset$$

Recaping: The Backdoor Criterion

Story permit us to compute the causal effect of one variable on another, from data obtained by passive observations, with no interventions? Since we have decided to represent causal stories with graphs, the question becomes a graph-theoretical problem: Under what conditions is the structure of the causal graph sufficient for computing a causal effect from a given data set?

Winter 2023 6.

More Examples for Backdoors

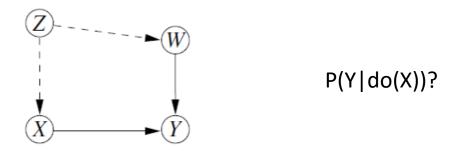

Figure 3.6: A graphical model representing the relationship between a new drug (X), recovery (Y), weight (W), and an unmeasured variable Z (socioeconomic status)

W is a backdoor. Therefore we can compute:

$$P(Y = y | do(X = x)) = \sum_{w} P(Y = y | X = x, W = w) P(W = w)$$

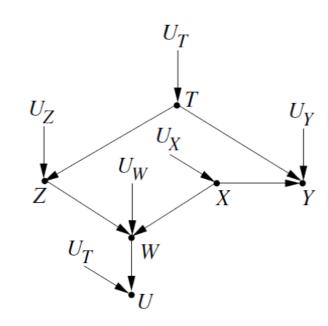

winter 2023

Examples

P(Y|do(X))?

No backdoors between X and Y and therefore: P(Y|do(X)) = P(Y|X)

What if we adjust for W? ... wrong!!!

But what if we want to determine P(Y | do(X), w)? What do we do with the spurious path $X \to W \leftarrow Z < T \to Y$?

if we condition on T, we would block the spurious path $X \to W \leftarrow Z \lt T \to Y$. We can compute:

$$P(Y = y | do(X = x), W = w) = \sum_{t} P(Y = y | X = x, W = w, T = t) P(T = t | W = w)$$

Example: W can be post-treatment pain

Adjusting for Colliders?

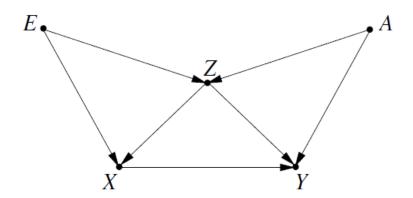

Figure 3.7: A graphical model in which the backdoor criterion requires that we condition on a collider (Z) in order to ascertain the effect of X on Y

There are 4 backdoor paths. We must adjust for Z, and one of E or A or both
