

Presentation for use with the textbook, *Algorithm Design and Applications*, by M. T. Goodrich and R. Tamassia, Wiley, 2015

Divide-and-Conquer

Grand Canyon from South Rim, 1941. Ansel Adams. U.S. government image. U.S. National Archives and Records Administration.

Application: Maxima Sets

- ◆ We can visualize the various trade-offs for optimizing two-dimensional data, such as points representing hotels according to their pool size and restaurant quality, by plotting each as a two-dimensional point, (x, y) , where x is the pool size and y is the restaurant quality score.
- ◆ We say that such a point is a **maximum point** in a set if there is no other point, (x', y') , in that set such that $x \leq x'$ and $y \leq y'$.
- ◆ The maximum points are the best potential choices based on these two dimensions and finding all of them is the **maxima set** problem.

We can efficiently find all the maxima points by divide-and-conquer. Here the set is $\{A, H, I, G, D\}$.

Divide-and-Conquer

- ◆ **Divide-and conquer** is a general algorithm design paradigm:
 - **Divide**: divide the input data S in two or more disjoint subsets S_1, S_2, \dots
 - **Conquer**: solve the subproblems recursively
 - **Combine**: combine the solutions for S_1, S_2, \dots , into a solution for S
- ◆ The base case for the recursion are subproblems of constant size
- ◆ Analysis can be done using **recurrence equations**

Merge-Sort Review

- ◆ Merge-sort on an input sequence S with n elements consists of three steps:
 - **Divide**: partition S into two sequences S_1 and S_2 of about $n/2$ elements each
 - **Conquer**: recursively sort S_1 and S_2
 - **Combine**: merge S_1 and S_2 into a unique sorted sequence

Algorithm *mergeSort(S)*

Input sequence S with n elements

Output sequence S sorted according to C

if $S.size() > 1$

$(S_1, S_2) \leftarrow partition(S, n/2)$

mergeSort(S_1)

mergeSort(S_2)

$S \leftarrow merge(S_1, S_2)$

Recurrence Equation Analysis

- ◆ The conquer step of merge-sort consists of merging two sorted sequences, each with $n/2$ elements and implemented by means of a doubly linked list, takes at most bn steps, for some constant b .
- ◆ Likewise, the basis case ($n < 2$) will take at b most steps.
- ◆ Therefore, if we let $T(n)$ denote the running time of merge-sort:

$$T(n) = \begin{cases} b & \text{if } n < 2 \\ 2T(n/2) + bn & \text{if } n \geq 2 \end{cases}$$

- ◆ We can therefore analyze the running time of merge-sort by finding a **closed form solution** to the above equation.
 - That is, a solution that has $T(n)$ only on the left-hand side.

Iterative Substitution

- ◆ In the iterative substitution, or “plug-and-chug,” technique, we iteratively apply the recurrence equation to itself and see if we can find a pattern:

$$\begin{aligned}T(n) &= 2T(n/2) + bn \\&= 2(2T(n/2^2)) + b(n/2) + bn \\&= 2^2 T(n/2^2) + 2bn \\&= 2^3 T(n/2^3) + 3bn \\&= 2^4 T(n/2^4) + 4bn \\&= \dots \\&= 2^i T(n/2^i) + ibn\end{aligned}$$

- ◆ Note that base, $T(n)=b$, case occurs when $2^i=n$. That is, $i = \log n$.

- ◆ So,
$$T(n) = bn + bn \log n$$

- ◆ Thus, $T(n)$ is $O(n \log n)$.

The Recursion Tree

- ◆ Draw the recursion tree for the recurrence relation and look for a pattern:

$$T(n) = \begin{cases} b & \text{if } n < 2 \\ 2T(n/2) + bn & \text{if } n \geq 2 \end{cases}$$

Total time = $bn + bn \log n$
(last level plus all previous levels)

Guess-and-Test Method

- ◆ In the guess-and-test method, we guess a closed form solution and then try to prove it is true by induction:

$$T(n) = \begin{cases} b & \text{if } n < 2 \\ 2T(n/2) + bn \log n & \text{if } n \geq 2 \end{cases}$$

- ◆ Guess: $T(n) < cn \log n$.

$$\begin{aligned} T(n) &= 2T(n/2) + bn \log n \\ &= 2(c(n/2) \log(n/2)) + bn \log n \\ &= cn(\log n - \log 2) + bn \log n \\ &= cn \log n - cn + bn \log n \end{aligned}$$

- ◆ Wrong: we cannot make this last line be less than $cn \log n$

Guess-and-Test Method, (cont.)

- ◆ Recall the recurrence equation:

$$T(n) = \begin{cases} b & \text{if } n < 2 \\ 2T(n/2) + bn \log n & \text{if } n \geq 2 \end{cases}$$

- ◆ Guess #2: $T(n) < cn \log^2 n$.

$$\begin{aligned} T(n) &= 2T(n/2) + bn \log n \\ &= 2(c(n/2) \log^2(n/2)) + bn \log n \\ &= cn(\log n - \log 2)^2 + bn \log n \\ &= cn \log^2 n - 2cn \log n + cn + bn \log n \\ &\leq cn \log^2 n \end{aligned}$$

- if $c > b$.

- ◆ So, $T(n)$ is $O(n \log^2 n)$.

- ◆ In general, to use this method, you need to have a good guess and you need to be good at induction proofs.

Master Method

- ◆ Many divide-and-conquer recurrence equations have the form:

$$T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \geq d \end{cases}$$

- ◆ The Master Theorem:

1. if $f(n)$ is $O(n^{\log_b a - \varepsilon})$, then $T(n)$ is $\Theta(n^{\log_b a})$
2. if $f(n)$ is $\Theta(n^{\log_b a} \log^k n)$, then $T(n)$ is $\Theta(n^{\log_b a} \log^{k+1} n)$
3. if $f(n)$ is $\Omega(n^{\log_b a + \varepsilon})$, then $T(n)$ is $\Theta(f(n))$,
provided $af(n/b) \leq \delta f(n)$ for some $\delta < 1$.

Master Method, Example 1

◆ The form:
$$T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \geq d \end{cases}$$

◆ The Master Theorem:

1. if $f(n)$ is $O(n^{\log_b a - \epsilon})$, then $T(n)$ is $\Theta(n^{\log_b a})$
2. if $f(n)$ is $\Theta(n^{\log_b a} \log^k n)$, then $T(n)$ is $\Theta(n^{\log_b a} \log^{k+1} n)$
3. if $f(n)$ is $\Omega(n^{\log_b a + \epsilon})$, then $T(n)$ is $\Theta(f(n))$,
provided $af(n/b) \leq \delta f(n)$ for some $\delta < 1$.

◆ Example:

$$T(n) = 4T(n/2) + n$$

Solution: $\log_b a = 2$, so case 1 says $T(n)$ is $O(n^2)$.

Master Method, Example 2

◆ The form:
$$T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \geq d \end{cases}$$

◆ The Master Theorem:

1. if $f(n)$ is $O(n^{\log_b a - \epsilon})$, then $T(n)$ is $\Theta(n^{\log_b a})$
2. if $f(n)$ is $\Theta(n^{\log_b a} \log^k n)$, then $T(n)$ is $\Theta(n^{\log_b a} \log^{k+1} n)$
3. if $f(n)$ is $\Omega(n^{\log_b a + \epsilon})$, then $T(n)$ is $\Theta(f(n))$,
provided $af(n/b) \leq \delta f(n)$ for some $\delta < 1$.

◆ Example:

$$T(n) = 2T(n/2) + n \log n$$

Solution: $\log_b a = 1$, so case 2 says $T(n)$ is $O(n \log^2 n)$.

Master Method, Example 3

◆ The form:
$$T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \geq d \end{cases}$$

◆ The Master Theorem:

1. if $f(n)$ is $O(n^{\log_b a - \epsilon})$, then $T(n)$ is $\Theta(n^{\log_b a})$
2. if $f(n)$ is $\Theta(n^{\log_b a} \log^k n)$, then $T(n)$ is $\Theta(n^{\log_b a} \log^{k+1} n)$
3. if $f(n)$ is $\Omega(n^{\log_b a + \epsilon})$, then $T(n)$ is $\Theta(f(n))$,
provided $af(n/b) \leq \delta f(n)$ for some $\delta < 1$.

◆ Example:

$$T(n) = T(n/3) + n \log n$$

Solution: $\log_b a = 0$, so case 3 says $T(n)$ is $O(n \log n)$.

Master Method, Example 4

◆ The form:
$$T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \geq d \end{cases}$$

◆ The Master Theorem:

1. if $f(n)$ is $O(n^{\log_b a - \epsilon})$, then $T(n)$ is $\Theta(n^{\log_b a})$
2. if $f(n)$ is $\Theta(n^{\log_b a} \log^k n)$, then $T(n)$ is $\Theta(n^{\log_b a} \log^{k+1} n)$
3. if $f(n)$ is $\Omega(n^{\log_b a + \epsilon})$, then $T(n)$ is $\Theta(f(n))$,
provided $af(n/b) \leq \delta f(n)$ for some $\delta < 1$.

◆ Example:

$$T(n) = 8T(n/2) + n^2$$

Solution: $\log_b a = 3$, so case 1 says $T(n)$ is $O(n^3)$.

Master Method, Example 5

◆ The form:
$$T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \geq d \end{cases}$$

◆ The Master Theorem:

1. if $f(n)$ is $O(n^{\log_b a - \epsilon})$, then $T(n)$ is $\Theta(n^{\log_b a})$
2. if $f(n)$ is $\Theta(n^{\log_b a} \log^k n)$, then $T(n)$ is $\Theta(n^{\log_b a} \log^{k+1} n)$
3. if $f(n)$ is $\Omega(n^{\log_b a + \epsilon})$, then $T(n)$ is $\Theta(f(n))$,
provided $af(n/b) \leq \delta f(n)$ for some $\delta < 1$.

◆ Example:

$$T(n) = 9T(n/3) + n^3$$

Solution: $\log_b a = 2$, so case 3 says $T(n)$ is $O(n^3)$.

Master Method, Example 6

◆ The form:
$$T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \geq d \end{cases}$$

◆ The Master Theorem:

1. if $f(n)$ is $O(n^{\log_b a - \epsilon})$, then $T(n)$ is $\Theta(n^{\log_b a})$
2. if $f(n)$ is $\Theta(n^{\log_b a} \log^k n)$, then $T(n)$ is $\Theta(n^{\log_b a} \log^{k+1} n)$
3. if $f(n)$ is $\Omega(n^{\log_b a + \epsilon})$, then $T(n)$ is $\Theta(f(n))$,
provided $af(n/b) \leq \delta f(n)$ for some $\delta < 1$.

◆ Example:

$$T(n) = T(n/2) + 1 \quad (\text{binary search})$$

Solution: $\log_b a = 0$, so case 2 says $T(n)$ is $O(\log n)$.

Master Method, Example 7

◆ The form:
$$T(n) = \begin{cases} c & \text{if } n < d \\ aT(n/b) + f(n) & \text{if } n \geq d \end{cases}$$

◆ The Master Theorem:

1. if $f(n)$ is $O(n^{\log_b a - \epsilon})$, then $T(n)$ is $\Theta(n^{\log_b a})$
2. if $f(n)$ is $\Theta(n^{\log_b a} \log^k n)$, then $T(n)$ is $\Theta(n^{\log_b a} \log^{k+1} n)$
3. if $f(n)$ is $\Omega(n^{\log_b a + \epsilon})$, then $T(n)$ is $\Theta(f(n))$,
provided $af(n/b) \leq \delta f(n)$ for some $\delta < 1$.

◆ Example:

$$T(n) = 2T(n/2) + \log n \quad (\text{heap construction})$$

Solution: $\log_b a = 1$, so case 1 says $T(n)$ is $O(n)$.

Sketch of Proof of the Master Theorem

- ◆ Using iterative substitution, let us see if we can find a pattern:

$$\begin{aligned}T(n) &= aT(n/b) + f(n) \\&= a(aT(n/b^2)) + f(n/b) + f(n) \\&= a^2T(n/b^2) + af(n/b) + f(n) \\&= a^3T(n/b^3) + a^2f(n/b^2) + af(n/b) + f(n) \\&= \dots \\&= a^{\log_b n}T(1) + \sum_{i=0}^{(\log_b n)-1} a^i f(n/b^i) \\&= n^{\log_b a}T(1) + \sum_{i=0}^{(\log_b n)-1} a^i f(n/b^i)\end{aligned}$$

- ◆ We then distinguish the three cases as
 - The first term is dominant
 - Each part of the summation is equally dominant
 - The summation is a geometric series

Integer Multiplication

◆ Algorithm: Multiply two n-bit integers I and J.

- Divide step: Split I and J into high-order and low-order bits

$$I = I_h 2^{n/2} + I_l$$

$$J = J_h 2^{n/2} + J_l$$

- We can then define $I * J$ by multiplying the parts and adding:

$$\begin{aligned} I * J &= (I_h 2^{n/2} + I_l) * (J_h 2^{n/2} + J_l) \\ &= I_h J_h 2^n + I_h J_l 2^{n/2} + I_l J_h 2^{n/2} + I_l J_l \end{aligned}$$

- So, $T(n) = 4T(n/2) + n$, which implies $T(n)$ is $O(n^2)$.
- But that is no better than the algorithm we learned in grade school.

An Improved Integer Multiplication Algorithm

9
x 1

◆ Algorithm: Multiply two n-bit integers I and J.

- Divide step: Split I and J into high-order and low-order bits

$$I = I_h 2^{n/2} + I_l$$

$$J = J_h 2^{n/2} + J_l$$

- Observe that there is a different way to multiply parts:

$$\begin{aligned} I * J &= I_h J_h 2^n + [(I_h - I_l)(J_l - J_h) + I_h J_h + I_l J_l] 2^{n/2} + I_l J_l \\ &= I_h J_h 2^n + [(I_h J_l - I_l J_l - I_h J_h + I_l J_h) + I_h J_h + I_l J_l] 2^{n/2} + I_l J_l \\ &= I_h J_h 2^n + (I_h J_l + I_l J_h) 2^{n/2} + I_l J_l \end{aligned}$$

- So, $T(n) = 3T(n/2) + n$, which implies $T(n)$ is $O(n^{\log_2 3})$, by the Master Theorem.
- Thus, $T(n)$ is $O(n^{1.585})$.

Solving the Maxima Set Problem

- ◆ Let us now return to the problem of finding a **maxima set** for a set, S , of n points in the plane.
- ◆ This problem is motivated from multi-objective optimization, where we are interested in optimizing choices that depend on multiple variables.
- ◆ For instance, in the introduction we used the example of someone wishing to optimize hotels based on the two variables of pool size and restaurant quality.
- ◆ A point is a **maximum point** in S if there is no other point, (x', y') , in S such that $x \leq x'$ and $y \leq y'$.

Divide-and-Conquer Solution

- ◆ Given a set, S , of n points in the plane, there is a simple divide-and-conquer algorithm for constructing the maxima set of points in S .
- ◆ If $n \leq 1$, the maxima set is just S itself.
- ◆ Otherwise, let p be the median point in S according to a lexicographic ordering of the points in S , that is, where we order based primarily on x -coordinates and then by y -coordinates if there are ties.
- ◆ Next, we recursively solve the maxima-set problem for the set of points on the left of this line and also for the points on the right.
- ◆ Given these solutions, the maxima set of points on the right are also maxima points for S .
- ◆ But some of the maxima points for the left set might be dominated by a point from the right, namely the point, q , that is leftmost.
- ◆ So then we do a scan of the left set of maxima, removing any points that are dominated by q , until reaching the point where q 's dominance extends.
- ◆ The union of remaining set of maxima from the left and the maxima set from the right is the set of maxima for S .

Example for the Combine Step

Pseudo-code

Algorithm MaximaSet(S):

Input: A set, S , of n points in the plane

Output: The set, M , of maxima points in S

if $n \leq 1$ **then**
 return S

Let p be the median point in S , by lexicographic (x, y) -coordinates

Let L be the set of points lexicographically less than p in S

Let G be the set of points lexicographically greater than or equal to p in S

$M_1 \leftarrow \text{MaximaSet}(L)$

$M_2 \leftarrow \text{MaximaSet}(G)$

Let q be the lexicographically smallest point in M_2

for each point, r , in M_1 **do**

if $x(r) \leq x(q)$ **and** $y(r) \leq y(q)$ **then**

 Remove r from M_1

return $M_1 \cup M_2$

A Little Implementation Detail

- ◆ Before we analyze the divide-and-conquer maxima-set algorithm, there is a little implementation detail that we need to work out.
- ◆ Namely, there is the issue of how to efficiently find the point, p , that is the median point in a lexicographical ordering of the points in S according to their (x, y) -coordinates.
- ◆ There are two immediate possibilities:
- ◆ One choice is to use a linear-time median-finding algorithm, such as that given in Section 9.2. This achieves a good asymptotic running time, but adds some implementation complexity.
- ◆ Another choice is to sort the points in S lexicographically by their (x, y) -coordinates as a preprocessing step, prior to calling the MaxmaSet algorithm on S . Given this preprocessing step, the median point is simply the point in the middle of the list.

Analysis

- ◆ In either case, the rest of the non-recursive steps can be performed in $O(n)$ time, so this implies that, ignoring floor and ceiling functions (as allowed by the analysis of Exercise C-11.5), the running time for the divide-and-conquer maxima-set algorithm can be specified as follows (where b is a constant):

$$T(n) = \begin{cases} b & \text{if } n < 2 \\ 2T(n/2) + bn & \text{if } n \geq 2 \end{cases}$$

- ◆ Thus, according to the Master Theorem, this algorithm runs in $O(n \log n)$ time.
